Glossary of Terms and Qualifiers

Work Order: 15-01-1404 Page 1 of 1

Qualifiers	Definition
*	See applicable analysis comment.
<	Less than the indicated value.
>	Greater than the indicated value.
1	Surrogate compound recovery was out of control due to a required sample dilution. Therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to suspected matrix interference. The associated LCS recovery was in control.
4	The MS/MSD RPD was out of control due to suspected matrix interference.
5	The PDS/PDSD or PES/PESD associated with this batch of samples was out of control due to suspected matrix interference.
6	Surrogate recovery below the acceptance limit.
7	Surrogate recovery above the acceptance limit.
B	Analyte was present in the associated method blank.
BU	Sample analyzed after holding time expired.
BV	Sample received after holding time expired.
E	Concentration exceeds the calibration range.
ET	Sample was extracted past end of recommended max. holding time.
HD	The chromatographic pattern was inconsistent with the profile of the reference fuel standard.
HDH	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but heavier hydrocarbons were also present (or detected).
HDL	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but lighter hydrocarbons were also present (or detected).
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
JA	Analyte positively identified but quantitation is an estimate.
ME	LCS Recovery Percentage is within Marginal Exceedance (ME) Control Limit range (+/- 4 SD from the mean).
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
SG	The sample extract was subjected to Silica Gel treatment prior to analysis.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are reported on a wet weight basis.

Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.

A calculated total result (Example: Total Pesticides) is the summation of each component concentration and/or, if "J" flags are reported, estimated concentration. Component concentrations showing not detected (ND) are summed into the calculated total result as zero concentrations.

Eurofins Calscience, Inc. (Calscience) certifies that the test results provided in this report meet all NELAC requirements for parameters for which accreditation is required or available. Any exceptions to NELAC requirements are noted in the case narrative. The original report of subcontracted analyses, if any, is attached to this report. The results in this report are limited to the sample(s) tested and any reproduction thereof must be made in its entirety. The client or recipient of this report is specifically prohibited from making material changes to said report and, to the extent that such changes are made, Calscience is not responsible, legally or otherwise. The client or recipient agrees to indemnify Calscience for any defense to any litigation which may arise.

Work Order Narrative

Work Order: 15-01-1511 Page 1 of 1

Condition Upon Receipt:

Samples were received under Chain-of-Custody (COC) on 01/24/15. They were assigned to Work Order 15-01-1511.

Unless otherwise noted on the Sample Receiving forms all samples were received in good condition and within the recommended EPA temperature criteria for the methods noted on the COC. The COC and Sample Receiving Documents are integral elements of the analytical report and are presented at the back of the report.

Holding Times:

All samples were analyzed within prescribed holding times (HT) and/or in accordance with the Calscience Sample Acceptance Policy unless otherwise noted in the analytical report and/or comprehensive case narrative, if required.

Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.

Quality Control:

All quality control parameters (QC) were within established control limits except where noted in the QC summary forms or described further within this report.

Subcontractor Information:

Unless otherwise noted below (or on the subcontract form), no samples were subcontracted.

Additional Comments:

Air - Sorbent-extracted air methods (EPA TO-4A, EPA TO-10, EPA TO-13A, EPA TO-17): Analytical results are converted from mass/sample basis to mass/volume basis using client-supplied air volumes.

Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are always reported on a wet weight basis.

EPA 6010B Silicon LCS recovery was below the control limits. Silicon was detected in each of the samples. The results may be biased low.

Analytical Report

SWCA Environmental Consultants
6200 UTSA Blvd., Suite 102
San Antonio, TX 78249-1618

Project: EAA 27122

Date Received: 01/24/15
Work Order: 15-01-1511
Preparation: EPA 3005A Filt.
Method: EPA 6010B
Units: mg/L

Client Sample Number	Lab Sample Number	Date/Time Collected	Matrix	Instrument	Date Prepared	Date/Time Analyzed	QC Batch ID
HCS 210 Peak	**15-01-1511-1-D**	**01/22/15 16:28**	**Aqueous**	**ICP 7300**	**01/26/15**	**01/27/15 17:55**	**150126L6FF**

Comment(s): - Results were evaluated to the MDL (DL), concentrations >= to the MDL (DL) but < RL (LOQ), if found, are qualified with a "J" flag.

Parameter	Result	RL	MDL	DF	Qualifiers
Calcium	19.2	0.100	0.0118	1.00	
Magnesium	2.17	0.100	0.00336	1.00	B
Potassium	1.56	0.500	0.103	1.00	
Sodium	1.04	0.500	0.103	1.00	
Strontium	0.0978	0.0300	0.00277	1.00	
Silicon	1.07	0.0500	0.0279	1.00	

Client Sample Number	Lab Sample Number	Date/Time Collected	Matrix	Instrument	Date Prepared	Date/Time Analyzed	QC Batch ID
HCS 240 Peak	**15-01-1511-2-D**	**01/22/15 16:51**	**Aqueous**	**ICP 7300**	**01/26/15**	**01/27/15 18:00**	**150126L6FF**

Comment(s): - Results were evaluated to the MDL (DL), concentrations >= to the MDL (DL) but < RL (LOQ), if found, are qualified with a "J" flag.

Parameter	Result	RL	MDL	DF	Qualifiers
Calcium	75.6	0.100	0.0118	1.00	
Magnesium	14.6	0.100	0.00336	1.00	B

Glossary of Terms and Qualifiers

Work Order: 15-01-1511 Page 1 of 1

Qualifiers	Definition
*	See applicable analysis comment.
<	Less than the indicated value.
>	Greater than the indicated value.
1	Surrogate compound recovery was out of control due to a required sample dilution. Therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to suspected matrix interference. The associated LCS recovery was in control.
4	The MS/MSD RPD was out of control due to suspected matrix interference.
5	The PDS/PDSD or PES/PESD associated with this batch of samples was out of control due to suspected matrix interference.
6	Surrogate recovery below the acceptance limit.
7	Surrogate recovery above the acceptance limit.
B	Analyte was present in the associated method blank.
BU	Sample analyzed after holding time expired.
BV	Sample received after holding time expired.
E	Concentration exceeds the calibration range.
ET	Sample was extracted past end of recommended max. holding time.
HD	The chromatographic pattern was inconsistent with the profile of the reference fuel standard.
HDH	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but heavier hydrocarbons were also present (or detected).
HDL	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but lighter hydrocarbons were also present (or detected).
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
JA	Analyte positively identified but quantitation is an estimate.
ME	LCS Recovery Percentage is within Marginal Exceedance (ME) Control Limit range (+/- 4 SD from the mean).
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
SG	The sample extract was subjected to Silica Gel treatment prior to analysis.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are reported on a wet weight basis.

Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.

A calculated total result (Example: Total Pesticides) is the summation of each component concentration and/or, if "J" flags are reported, estimated concentration. Component concentrations showing not detected (ND) are summed into the calculated total result as zero concentrations.

WORK ORDER #: 15-01-☑☑☑☑

SAMPLE RECEIPT FORM

Cooler 1 of 12

CLIENT: SWCA DATE: 01/24/15

TEMPERATURE: Thermometer ID: SC4 (Criteria: 0.0 °C – 6.0 °C, not frozen except sediment/tissue)

Temperature 3.1 °C + 0.2 °C (CF) = 3.3 °C ☑ Blank ☐ Sample

☐ Sample(s) outside temperature criteria (PM/APM contacted by: _____)

☐ Sample(s) outside temperature criteria but received on ice/chilled on same day of sampling.

☐ **Received at ambient temperature, placed on ice for transport by Courier.**

Ambient Temperature: ☐ Air ☐ Filter **Checked by:** SB2

CUSTODY SEALS INTACT:

☑ Cooler ☐_____ ☐ No (Not Intact) ☐ Not Present ☐ N/A **Checked by:** SB2

☐ Sample ☐_____ ☐ No (Not Intact) ☑ Not Present **Checked by:** 681

SAMPLE CONDITION:	Yes	No	N/A
Chain-Of-Custody (COC) document(s) received with samples	☑	☐	☐
COC document(s) received complete	☑	☐	☐
☐ Collection date/time, matrix, and/or # of containers logged in based on sample labels.			
☐ No analysis requested. ☐ Not relinquished. ☐ No date/time relinquished.			
Sampler's name indicated on COC	☑	☐	☐
Sample container label(s) consistent with COC	☐	☑	☐
Sample container(s) intact and good condition	☐	☑	☐
Proper containers and sufficient volume for analyses requested	☑	☐	☐
Analyses received within holding time	☑	☐	☐
Aqueous samples received within 15-minute holding time			
☐ pH ☐ Residual Chlorine ☐ Dissolved Sulfides ☐ Dissolved Oxygen	☐	☐	☑
Proper preservation noted on COC or sample container	☑	☐	☐
☐ Unpreserved vials received for Volatiles analysis			
Volatile analysis container(s) free of headspace	☑	☐	☐
Tedlar bag(s) free of condensation	☐	☐	☑

SAMPLE ANOMALY FORM

SAMPLES - CONTAINERS & LABELS:

Comments:

- ☐ **Sample(s) NOT RECEIVED but listed on COC**
- ☐ **Sample(s) received but NOT LISTED on COC**
- ☐ **Holding time expired** – list sample ID(s) and test
- ☐ **Insufficient quantities for analysis** – list test
- ☐ **Improper container(s) used** – list test
- ☐ **Improper preservative used** – list test
- ☐ **No preservative noted on COC or label** – list test & notify lab
- ☐ **Sample labels illegible** – note test/container type
- ☑ **Sample label(s) do not match COC** – Note in comments
  - ☑ **Sample ID**
  - ☑ **Date and/or Time Collected**
  - ☐ **Project Information**
  - ☐ **# of Container(s)**
  - ☐ **Analysis**
- ☑ **Sample container(s) compromised** – Note in comments
  - ☐ **Water present in sample container**
  - ☑ **Broken**
- ☐ **Sample container(s) not labeled**
- ☐ **Air sample container(s) compromised** – Note in comments
  - ☐ **Flat**
  - ☐ **Very low in volume**
  - ☐ **Leaking (Not transferred - duplicate bag submitted)**
  - ☐ **Leaking (transferred into Calscience Tedlar® Bag*)**
  - ☐ **Leaking (transferred into Client's Tedlar® Bag*)**
- ☐ **Other:** _____

(-4) Collection time per label is 17:10.

(-1) labeled as HCS260 Trail Collection date & time matched.

(-11) 1 of 2 250CGB w. H_2SO_4 received broken.

HEADSPACE – Containers with Bubble > 6mm or ¼ inch:

Work Order Narrative

Work Order: 15-05-0402 Page 1 of 1

Condition Upon Receipt:

Samples were received under Chain-of-Custody (COC) on 05/07/15. They were assigned to Work Order 15-05-0402.

Unless otherwise noted on the Sample Receiving forms all samples were received in good condition and within the recommended EPA temperature criteria for the methods noted on the COC. The COC and Sample Receiving Documents are integral elements of the analytical report and are presented at the back of the report.

Holding Times:

All samples were analyzed within prescribed holding times (HT) and/or in accordance with the Calscience Sample Acceptance Policy unless otherwise noted in the analytical report and/or comprehensive case narrative, if required.

Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.

Quality Control:

All quality control parameters (QC) were within established control limits except where noted in the QC summary forms or described further within this report.

Subcontractor Information:

Unless otherwise noted below (or on the subcontract form), no samples were subcontracted.

Additional Comments:

Air - Sorbent-extracted air methods (EPA TO-4A, EPA TO-10, EPA TO-13A, EPA TO-17): Analytical results are converted from mass/sample basis to mass/volume basis using client-supplied air volumes.

Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are always reported on a wet weight basis.

Analytical Report

SWCA Environmental Consultants
6200 UTSA Blvd., Suite 102
San Antonio, TX 78249-1618

Date Received: 05/07/15
Work Order: 15-05-0402
Preparation: N/A
Method: EPA 300.0
Units: mg/L

Project: EAA 27122

Client Sample Number	Lab Sample Number	Date/Time Collected	Matrix	Instrument	Date Prepared	Date/Time Analyzed	QC Batch ID
HSM 210 Lead	**15-05-0402-1-I**	**05/05/15 22:10**	**Aqueous**	**IC 15**	**N/A**	**05/07/15 14:53**	**150507L01**

Comment(s): - Results were evaluated to the MDL (DL), concentrations >= to the MDL (DL) but < RL (LOQ), if found, are qualified with a "J" flag.

Parameter	Result	RL	MDL	DF	Qualifiers
Fluoride	0.21	0.10	0.025	1.00	
Chloride	26	1.0	0.12	1.00	
Bromide	0.15	0.10	0.037	1.00	
Nitrate (as N)	0.38	0.10	0.025	1.00	
Sulfate	36	1.0	0.19	1.00	

Client Sample Number	Lab Sample Number	Date/Time Collected	Matrix	Instrument	Date Prepared	Date/Time Analyzed	QC Batch ID
HSM 230 Lead	**15-05-0402-2-I**	**05/05/15 22:20**	**Aqueous**	**IC 15**	**N/A**	**05/07/15 15:09**	**150507L01**

Comment(s): - Results were evaluated to the MDL (DL), concentrations >= to the MDL (DL) but < RL (LOQ), if found, are qualified with a "J" flag.

Parameter	Result	RL	MDL	DF	Qualifiers
Fluoride	0.096	0.10	0.025	1.00	J
Chloride	7.2	1.0	0.12	1.00	
Bromide	ND	0.10	0.037	1.00

Glossary of Terms and Qualifiers

Work Order: 15-05-0402 Page 1 of 1

Qualifiers	Definition
*	See applicable analysis comment.
<	Less than the indicated value.
>	Greater than the indicated value.
1	Surrogate compound recovery was out of control due to a required sample dilution. Therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to suspected matrix interference. The associated LCS recovery was in control.
4	The MS/MSD RPD was out of control due to suspected matrix interference.
5	The PDS/PDSD or PES/PESD associated with this batch of samples was out of control due to suspected matrix interference.
6	Surrogate recovery below the acceptance limit.
7	Surrogate recovery above the acceptance limit.
B	Analyte was present in the associated method blank.
BU	Sample analyzed after holding time expired.
BV	Sample received after holding time expired.
CI	See case narrative.
E	Concentration exceeds the calibration range.
ET	Sample was extracted past end of recommended max. holding time.
HD	The chromatographic pattern was inconsistent with the profile of the reference fuel standard.
HDH	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but heavier hydrocarbons were also present (or detected).
HDL	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but lighter hydrocarbons were also present (or detected).
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
JA	Analyte positively identified but quantitation is an estimate.
ME	LCS Recovery Percentage is within Marginal Exceedance (ME) Control Limit range (+/- 4 SD from the mean).
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
SG	The sample extract was subjected to Silica Gel treatment prior to analysis.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are reported on a wet weight basis.

Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.

A calculated total result (Example: Total Pesticides) is the summation of each component concentration and/or, if "J" flags are reported, estimated concentration. Component concentrations showing not detected (ND) are summed into the calculated total result as zero concentrations.

SAMPLE ANOMALY REPORT

DATE: 05 / 07 / 2015

SAMPLES, CONTAINERS, AND LABELS:

Comments

- ☐ Sample(s) NOT RECEIVED but listed on COC
- ☐ Sample(s) received but NOT LISTED on COC
- ☐ Holding time expired (list client or ECI sample ID and analysis)
- ☐ Insufficient sample amount for requested analysis (list analysis)
- ☐ Improper container(s) used (list analysis)
- ☐ Improper preservative used (list analysis)
- ☐ No preservative noted on COC or label (list analysis and notify lab)
- ☐ Sample container(s) not labeled
- ☐ Client sample label(s) illegible (list container type and analysis)
- ☑ Client sample label(s) do not match COC (comment)
  - ☐ Project information
  - ☐ Client sample ID
  - ☐ Sampling date and/or time
  - ☑ Number of container(s)
  - ☑ Requested analysis
- ☐ Sample container(s) compromised (comment)
  - ☐ Broken
  - ☐ Water present in sample container
- ☐ Air sample container(s) compromised (comment)
  - ☐ Flat
  - ☐ Very low in volume
  - ☐ Leaking (not transferred; duplicate bag submitted)
  - ☐ Leaking (transferred into ECI Tedlar™ bags*)
  - ☐ Leaking (transferred into client's Tedlar™ bags*)

(-24) FDHSM 23D Trail received only 6 of 9 containers
Not received: 2 of 3 vials (8260)
1 liter Amber Glass (8270)

1 Liter Amber Glass w/ H_2SO_4 (TKN) received not full (~400ml)

(-15) TB06 received vial for 8260 (requested 8270).

* Transferred at client's request.

ANALYTICAL REPORT

November 03, 2015

Client:
Phil Pearce
6200 UTSA Blvd Ste 102
San Antonio, TX 78249 Fax #: NA

Sample Location: FDHSM210 TRAIL
Sample Number: AA97956
Sample Matrix: Non Potable Water

Collection Date/Time: 10/23/15 20:35
Receipt Date/Time: 10/26/15 08:32

CASE NARRATIVE

This report provides results related only to the referenced sample ID numbers. All samples were received in acceptable condition unless otherwise noted.
For questions regarding this report, please contact Greg Mateo, Laboratory Supervisor, at (210) 302-3290.

Analysis identified with a "√" complies with NELAP requirements unless otherwise specified in the case narrative .

Sample Comments: Exceeded hold time, per customer proceed.

ANALYTICAL RESULTS

	Analyses	NELAC	Analysis Method	Result	Units	Qualifier	Reporting Limit	QC Batch Number	Analysis Date	Analysis Time	Analyst

Work Order Narrative

Work Order: 15-10-1856 Page 1 of 1

Condition Upon Receipt:

Samples were received under Chain-of-Custody (COC) on 10/24/15. They were assigned to Work Order 15-10-1856.

Unless otherwise noted on the Sample Receiving forms all samples were received in good condition and within the recommended EPA temperature criteria for the methods noted on the COC. The COC and Sample Receiving Documents are integral elements of the analytical report and are presented at the back of the report.

Holding Times:

All samples were analyzed within prescribed holding times (HT) and/or in accordance with the Calscience Sample Acceptance Policy unless otherwise noted in the analytical report and/or comprehensive case narrative, if required.

Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.

Quality Control:

All quality control parameters (QC) were within established control limits except where noted in the QC summary forms or described further within this report.

Subcontractor Information:

Unless otherwise noted below (or on the subcontract form), no samples were subcontracted.

Additional Comments:

Air - Sorbent-extracted air methods (EPA TO-4A, EPA TO-10, EPA TO-13A, EPA TO-17): Analytical results are converted from mass/sample basis to mass/volume basis using client-supplied air volumes.

Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are always reported on a wet weight basis.

Glossary of Terms and Qualifiers

Work Order: 15-10-1856 Page 1 of 1

Qualifiers	Definition
*	See applicable analysis comment.
<	Less than the indicated value.
>	Greater than the indicated value.
1	Surrogate compound recovery was out of control due to a required sample dilution. Therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to suspected matrix interference. The associated LCS recovery was in control.
4	The MS/MSD RPD was out of control due to suspected matrix interference.
5	The PDS/PDSD or PES/PESD associated with this batch of samples was out of control due to suspected matrix interference.
6	Surrogate recovery below the acceptance limit.
7	Surrogate recovery above the acceptance limit.
B	Analyte was present in the associated method blank.
BU	Sample analyzed after holding time expired.
BV	Sample received after holding time expired.
CI	See case narrative.
E	Concentration exceeds the calibration range.
ET	Sample was extracted past end of recommended max. holding time.
HD	The chromatographic pattern was inconsistent with the profile of the reference fuel standard.
HDH	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but heavier hydrocarbons were also present (or detected).
HDL	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but lighter hydrocarbons were also present (or detected).
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
JA	Analyte positively identified but quantitation is an estimate.
ME	LCS Recovery Percentage is within Marginal Exceedance (ME) Control Limit range (+/- 4 SD from the mean).
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
SG	The sample extract was subjected to Silica Gel treatment prior to analysis.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are reported on a wet weight basis.

Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.

A calculated total result (Example: Total Pesticides) is the summation of each component concentration and/or, if "J" flags are reported, estimated concentration. Component concentrations showing not detected (ND) are summed into the calculated total result as zero concentrations.

Inorganic Data Qualifiers

*	The result is an outlier. See case narrative.
#	The control limit criteria is not applicable. See case narrative.
B	The analyte was found in the associated method blank at a level that is significant relative to the sample result as defined by the DOD or NELAC standards.
E	The result is an estimate amount because the value exceeded the instrument calibration range.
J	The result is an estimated value.
U	The analyte was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL. *DOD-QSM 4.2 definition* : Analyte was not detected and is reported as less than the LOD or as defined by the project. The detection limit is adjusted for dilution.
i	The MRL/MDL or LOQ/LOD is elevated due to a matrix interference.
X	See case narrative.
Q	See case narrative. One or more quality control criteria was outside the limits.
H	The holding time for this test is immediately following sample collection. The samples were analyzed as soon as possible after receipt by the laboratory.

Metals Data Qualifiers

#	The control limit criteria is not applicable. See case narrative.
J	The result is an estimated value.
E	The percent difference for the serial dilution was greater than 10%, indicating a possible matrix interference in the sample.
M	The duplicate injection precision was not met.
N	The Matrix Spike sample recovery is not within control limits. See case narrative.
S	The reported value was determined by the Method of Standard Additions (MSA).
U	The analyte was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL. *DOD-QSM 4.2 definition* : Analyte was not detected and is reported as less than the LOD or as defined by the project. The detection limit is adjusted for dilution.
W	The post-digestion spike for furnace AA analysis is out of control limits, while sample absorbance is less than 50% of spike absorbance.
i	The MRL/MDL or LOQ/LOD is elevated due to a matrix interference.
X	See case narrative.
+	The correlation coefficient for the MSA is less than 0.995.
Q	See case narrative. One or more quality control criteria was outside the limits.

Organic Data Qualifiers

*	The result is an outlier. See case narrative.
#	The control limit criteria is not applicable. See case narrative.
A	A tentatively identified compound, a suspected aldol-condensation product.
B	The analyte was found in the associated method blank at a level that is significant relative to the sample result as defined by the DOD or NELAC standards.
C	The analyte was qualitatively confirmed using GC/MS techniques, pattern recognition, or by comparing to historical data.
D	The reported result is from a dilution.
E	The result is an estimated value.
J	The result is an estimated value.
N	The result is presumptive. The analyte was tentatively identified, but a confirmation analysis was not performed.
P	The GC or HPLC confirmation criteria was exceeded. The relative percent difference is greater than 40% between the two analytical results.
U	The analyte was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL. *DOD-QSM 4.2 definition* : Analyte was not detected and is reported as less than the LOD or as defined by the project. The detection limit is adjusted for dilution.
i	The MRL/MDL or LOQ/LOD is elevated due to a chromatographic interference.
X	See case narrative.
Q	See case narrative. One or more quality control criteria was outside the limits.

Additional Petroleum Hydrocarbon Specific Qualifiers

F	The chromatographic fingerprint of the sample matches the elution pattern of the calibration standard.
L	The chromatographic fingerprint of the sample resembles a petroleum product, but the elution pattern indicates the presence of a greater amount of lighter molecular weight constituents than the calibration standard.
H	The chromatographic fingerprint of the sample resembles a petroleum product, but the elution pattern indicates the presence of a greater amount of heavier molecular weight constituents than the calibration standard.
O	The chromatographic fingerprint of the sample resembles an oil, but does not match the calibration standard.
Y	The chromatographic fingerprint of the sample resembles a petroleum product eluting in approximately the correct carbon range, but the elution pattern does not match the calibration standard.
Z	The chromatographic fingerprint does not resemble a petroleum product.

ALS ENVIRONMENTAL

Client:	Eurofins Calscience Environmental Laboratory	**Service Request No.:**	K1512169
Project:	15-10-1856	**Date Received:**	10/27/15
Sample Matrix:	Water		

Case Narrative

All analyses were performed consistent with the quality assurance program of ALS Environmental. This report contains analytical results for samples designated for Tier II data deliverables. When appropriate to the method, method blank results have been reported with each analytical test. Surrogate recoveries have been reported for all applicable organic analyses. Additional quality control analyses reported herein include: Laboratory Control Sample (LCS), and Laboratory/Duplicate Laboratory Control Sample (LCS/DLCS).

Sample Receipt

Eight water samples were received for analysis at ALS Environmental on 10/27/15. The samples were received in good condition and consistent with the accompanying chain of custody form. The samples were stored in a refrigerator at 4ºC upon receipt at the laboratory.

Steroids and Endocrine Disrupting Compounds by Method 1694

Elevated Detection Limits:
Samples HCS 210 Lead and HCS 250 Lead required dilution due to the presence of elevated levels of target analyte. The reporting limits were adjusted to reflect the dilution.

No other anomalies associated with the analysis of these samples were observed.

Work Order Narrative

Work Order: 15-10-1995 Page 1 of 1

Condition Upon Receipt:

Samples were received under Chain-of-Custody (COC) on 10/27/15. They were assigned to Work Order 15-10-1995.

Unless otherwise noted on the Sample Receiving forms all samples were received in good condition and within the recommended EPA temperature criteria for the methods noted on the COC. The COC and Sample Receiving Documents are integral elements of the analytical report and are presented at the back of the report.

Holding Times:

All samples were analyzed within prescribed holding times (HT) and/or in accordance with the Calscience Sample Acceptance Policy unless otherwise noted in the analytical report and/or comprehensive case narrative, if required.

Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.

Quality Control:

All quality control parameters (QC) were within established control limits except where noted in the QC summary forms or described further within this report.

Subcontractor Information:

Unless otherwise noted below (or on the subcontract form), no samples were subcontracted.

Additional Comments:

Air - Sorbent-extracted air methods (EPA TO-4A, EPA TO-10, EPA TO-13A, EPA TO-17): Analytical results are converted from mass/sample basis to mass/volume basis using client-supplied air volumes.

Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are always reported on a wet weight basis.

Analytical Report

SWCA Environmental Consultants
6200 UTSA Blvd., Suite 102
San Antonio, TX 78249-1618

Date Received: 10/27/15
Work Order: 15-10-1995
Preparation: EPA 3005A Filt.
Method: EPA 6010B
Units: mg/L

Project: EAA 27122

Client Sample Number	Lab Sample Number	Date/Time Collected	Matrix	Instrument	Date Prepared	Date/Time Analyzed	QC Batch ID
HCS 270 Trail	**15-10-1995-7-F**	**10/23/15 17:34**	**Aqueous**	**ICP 7300**	**10/28/15**	**10/30/15 19:33**	**151028LA8F**

Comment(s): - Results were evaluated to the MDL (DL), concentrations >= to the MDL (DL) but < RL (LOQ), if found, are qualified with a "J" flag.

Parameter	Result	RL	MDL	DF	Qualifiers
Calcium	73.8	0.100	0.0118	1.00	B
Magnesium	15.3	0.100	0.00336	1.00	
Potassium	2.04	0.500	0.103	1.00	
Sodium	13.1	0.500	0.103	1.00	
Strontium	0.605	0.0300	0.00277	1.00	
Silicon	5.52	0.0500	0.0279	1.00	

Client Sample Number	Lab Sample Number	Date/Time Collected	Matrix	Instrument	Date Prepared	Date/Time Analyzed	QC Batch ID

Analytical Report

SWCA Environmental Consultants
6200 UTSA Blvd., Suite 102
San Antonio, TX 78249-1618

Date Received: 10/27/15
Work Order: 15-10-1995
Preparation: EPA 3005A Filt.
Method: EPA 6020
Units: mg/L

Project: EAA 27122

Client Sample Number	Lab Sample Number	Date/Time Collected	Matrix	Instrument	Date Prepared	Date/Time Analyzed	QC Batch ID
HCS 270 Trail	**15-10-1995-7-F**	**10/23/15 17:34**	**Aqueous**	**ICP/MS 03**	**10/28/15**	**10/30/15 23:17**	**151028LA4F**

Comment(s): - Results were evaluated to the MDL (DL), concentrations >= to the MDL (DL) but < RL (LOQ), if found, are qualified with a "J" flag.

HCS 260 Trail	**15-10-1995-6**	**10/23/15 16:50**	**Aqueous**

Comment(s): (24) - Results were evaluated to the MDL (DL), concentrations >= to the MDL (DL) but < RL (LOQ), if found, are qualified with a "J" flag.
(313) - The reporting limit is elevated resulting from matrix interference.

Comment(s): (24) - Results were evaluated to the MDL (DL), concentrations >= to the MDL (DL) but < RL (LOQ), if found, are qualified with a "J" flag.
(313) - The reporting limit is elevated resulting from matrix interference.

Analytical Report

SWCA Environmental Consultants
6200 UTSA Blvd., Suite 102
San Antonio, TX 78249-1618
Project: EAA 27122

Date Received: 10/27/15
Work Order: 15-10-1995

Client Sample Number	Lab Sample Number	Date/Time Collected	Matrix
HSM 210 Peak	**15-10-1995-28**	**10/23/15 17:02**	**Aqueous**

Comment(s): (24) - Results were evaluated to the MDL (DL), concentrations >= to the MDL (DL) but < RL (LOQ), if found, are qualified with a "J" flag.
(313) - The reporting limit is elevated resulting from matrix interference.

Parameter	Results	RL	MDL	DF	Qualifiers	Units	Date Prepared	Date Analyzed	Method

Glossary of Terms and Qualifiers

Work Order: 15-10-1995 Page 1 of 1

Qualifiers	Definition
*	See applicable analysis comment.
<	Less than the indicated value.
>	Greater than the indicated value.
1	Surrogate compound recovery was out of control due to a required sample dilution. Therefore, the sample data was reported without further clarification.
2	Surrogate compound recovery was out of control due to matrix interference. The associated method blank surrogate spike compound was in control and, therefore, the sample data was reported without further clarification.
3	Recovery of the Matrix Spike (MS) or Matrix Spike Duplicate (MSD) compound was out of control due to suspected matrix interference. The associated LCS recovery was in control.
4	The MS/MSD RPD was out of control due to suspected matrix interference.
5	The PDS/PDSD or PES/PESD associated with this batch of samples was out of control due to suspected matrix interference.
6	Surrogate recovery below the acceptance limit.
7	Surrogate recovery above the acceptance limit.
B	Analyte was present in the associated method blank.
BU	Sample analyzed after holding time expired.
BV	Sample received after holding time expired.
CI	See case narrative.
E	Concentration exceeds the calibration range.
ET	Sample was extracted past end of recommended max. holding time.
HD	The chromatographic pattern was inconsistent with the profile of the reference fuel standard.
HDH	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but heavier hydrocarbons were also present (or detected).
HDL	The sample chromatographic pattern for TPH matches the chromatographic pattern of the specified standard but lighter hydrocarbons were also present (or detected).
J	Analyte was detected at a concentration below the reporting limit and above the laboratory method detection limit. Reported value is estimated.
JA	Analyte positively identified but quantitation is an estimate.
ME	LCS Recovery Percentage is within Marginal Exceedance (ME) Control Limit range (+/- 4 SD from the mean).
ND	Parameter not detected at the indicated reporting limit.
Q	Spike recovery and RPD control limits do not apply resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater.
SG	The sample extract was subjected to Silica Gel treatment prior to analysis.
X	% Recovery and/or RPD out-of-range.
Z	Analyte presence was not confirmed by second column or GC/MS analysis.

Solid - Unless otherwise indicated, solid sample data is reported on a wet weight basis, not corrected for % moisture. All QC results are reported on a wet weight basis.

Any parameter identified in 40CFR Part 136.3 Table II that is designated as "analyze immediately" with a holding time of <= 15 minutes (40CFR-136.3 Table II, footnote 4), is considered a "field" test and the reported results will be qualified as being received outside of the stated holding time unless received at the laboratory within 15 minutes of the collection time.

A calculated total result (Example: Total Pesticides) is the summation of each component concentration and/or, if "J" flags are reported, estimated concentration. Component concentrations showing not detected (ND) are summed into the calculated total result as zero concentrations.

SAMPLE ANOMALY REPORT

DATE: 10 / 27 / 2015

SAMPLES, CONTAINERS, AND LABELS:

- ☑ Sample(s) NOT RECEIVED but listed on COC
- ☐ Sample(s) received but NOT LISTED on COC
- ☑ Holding time expired (list client or ECI sample ID and analysis)
- ☐ Insufficient sample amount for requested analysis (list analysis)
- ☐ Improper container(s) used (list analysis)
- ☐ Improper preservative used (list analysis)
- ☐ No preservative noted on COC or label (list analysis and notify lab)
- ☐ Sample container(s) not labeled
- ☐ Client sample label(s) illegible (list container type and analysis)
- ☐ Client sample label(s) do not match COC (comment)
  - ☐ Project information
  - ☐ Client sample ID
  - ☐ Sampling date and/or time
  - ☐ Number of container(s)
  - ☐ Requested analysis
- ☐ Sample container(s) compromised (comment)
  - ☐ Broken
  - ☐ Water present in sample container
- ☐ Air sample container(s) compromised (comment)
  - ☐ Flat
  - ☐ Very low in volume
  - ☐ Leaking (not transferred; duplicate bag submitted)
  - ☐ Leaking (transferred into ECI Tedlar™ bags*)
  - ☐ Leaking (transferred into client's Tedlar™ bags*)

* Transferred at client's request.

Comments

(-32) HSM 250 Peak not received.

Acronyms

ASTM	American Society for Testing and Materials
A2LA	American Association for Laboratory Accreditation
CARB	California Air Resources Board
CAS Number	Chemical Abstract Service registry Number
CFC	Chlorofluorocarbon
CFU	Colony-Forming Unit
DEC	Department of Environmental Conservation
DEQ	Department of Environmental Quality
DHS	Department of Health Services
DOE	Department of Ecology
DOH	Department of Health
EPA	U. S. Environmental Protection Agency
ELAP	Environmental Laboratory Accreditation Program
GC	Gas Chromatography
GC/MS	Gas Chromatography/Mass Spectrometry
LOD	Limit of Detection
LOQ	Limit of Quantitation
LUFT	Leaking Underground Fuel Tank
M	Modified
MCL	Maximum Contaminant Level is the highest permissible concentration of a substance allowed in drinking water as established by the USEPA.
MDL	Method Detection Limit
MPN	Most Probable Number
MRL	Method Reporting Limit
NA	Not Applicable
NC	Not Calculated
NCASI	National Council of the Paper Industry for Air and Stream Improvement
ND	Not Detected
NIOSH	National Institute for Occupational Safety and Health
PQL	Practical Quantitation Limit
RCRA	Resource Conservation and Recovery Act
SIM	Selected Ion Monitoring
TPH	Total Petroleum Hydrocarbons
tr	Trace level is the concentration of an analyte that is less than the PQL but greater than or equal to the MDL.

Return to Contents

Inorganic Data Qualifiers

*	The result is an outlier. See case narrative.
#	The control limit criteria is not applicable. See case narrative.
B	The analyte was found in the associated method blank at a level that is significant relative to the sample result as defined by the DOD or NELAC standards.
E	The result is an estimate amount because the value exceeded the instrument calibration range.
J	The result is an estimated value.
U	The analyte was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL. *DOD-QSM 4.2 definition* : Analyte was not detected and is reported as less than the LOD or as defined by the project. The detection limit is adjusted for dilution.
i	The MRL/MDL or LOQ/LOD is elevated due to a matrix interference.
X	See case narrative.
Q	See case narrative. One or more quality control criteria was outside the limits.
H	The holding time for this test is immediately following sample collection. The samples were analyzed as soon as possible after receipt by the laboratory.

Metals Data Qualifiers

#	The control limit criteria is not applicable. See case narrative.
J	The result is an estimated value.
E	The percent difference for the serial dilution was greater than 10%, indicating a possible matrix interference in the sample.
M	The duplicate injection precision was not met.
N	The Matrix Spike sample recovery is not within control limits. See case narrative.
S	The reported value was determined by the Method of Standard Additions (MSA).
U	The analyte was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL. *DOD-QSM 4.2 definition* : Analyte was not detected and is reported as less than the LOD or as defined by the project. The detection limit is adjusted for dilution.
W	The post-digestion spike for furnace AA analysis is out of control limits, while sample absorbance is less than 50% of spike absorbance.
i	The MRL/MDL or LOQ/LOD is elevated due to a matrix interference.
X	See case narrative.
+	The correlation coefficient for the MSA is less than 0.995.
Q	See case narrative. One or more quality control criteria was outside the limits.

Organic Data Qualifiers

*	The result is an outlier. See case narrative.
#	The control limit criteria is not applicable. See case narrative.
A	A tentatively identified compound, a suspected aldol-condensation product.
B	The analyte was found in the associated method blank at a level that is significant relative to the sample result as defined by the DOD or NELAC standards.
C	The analyte was qualitatively confirmed using GC/MS techniques, pattern recognition, or by comparing to historical data.
D	The reported result is from a dilution.
E	The result is an estimated value.
J	The result is an estimated value.
N	The result is presumptive. The analyte was tentatively identified, but a confirmation analysis was not performed.
P	The GC or HPLC confirmation criteria was exceeded. The relative percent difference is greater than 40% between the two analytical results.
U	The analyte was analyzed for, but was not detected ("Non-detect") at or above the MRL/MDL. *DOD-QSM 4.2 definition* : Analyte was not detected and is reported as less than the LOD or as defined by the project. The detection limit is adjusted for dilution.
i	The MRL/MDL or LOQ/LOD is elevated due to a chromatographic interference.
X	See case narrative.
Q	See case narrative. One or more quality control criteria was outside the limits.

Additional Petroleum Hydrocarbon Specific Qualifiers

F	The chromatographic fingerprint of the sample matches the elution pattern of the calibration standard.
L	The chromatographic fingerprint of the sample resembles a petroleum product, but the elution pattern indicates the presence of a greater amount of lighter molecular weight constituents than the calibration standard.
H	The chromatographic fingerprint of the sample resembles a petroleum product, but the elution pattern indicates the presence of a greater amount of heavier molecular weight constituents than the calibration standard.
O	The chromatographic fingerprint of the sample resembles an oil, but does not match the calibration standard.
Y	The chromatographic fingerprint of the sample resembles a petroleum product eluting in approximately the correct carbon range, but the elution pattern does not match the calibration standard.
Z	The chromatographic fingerprint does not resemble a petroleum product.

Analyses were performed according to our laboratory's NELAP-approved quality assurance program. A complete listing of specific NELAP-certified analytes, can be found in the certification section at www.ALSGlobal.com or at the accreditation bodies web site.
Please refer to the certification and/or accreditation body's web site if samples are submitted for compliance purposes. The states highlighted above, require the analysis be listed on the state certification if used for compliance purposes and if the method/anlayte is offered by that state.

ALS ENVIRONMENTAL

Client:	Eurofins Calscience Environmental Laboratory	**Service Request No.:**	K1512268
Project:	15-10-1995	**Date Received:**	10/29/15
Sample Matrix:	Water		

Case Narrative

All analyses were performed consistent with the quality assurance program of ALS Environmental. This report contains analytical results for samples designated for Tier II data deliverables. When appropriate to the method, method blank results have been reported with each analytical test. Surrogate recoveries have been reported for all applicable organic analyses. Additional quality control analyses reported herein include: Laboratory Control Sample (LCS), and Laboratory/Duplicate Laboratory Control Sample (LCS/DLCS).

Sample Receipt

Thirty-two water samples were received for analysis at ALS Environmental on 10/29/15. The samples were received in good condition and consistent with the accompanying chain of custody form. The samples were stored in a refrigerator at 4ºC upon receipt at the laboratory.

Steroids and Endocrine Disrupting Compounds by Method 1694

Elevated Detection Limits:
Samples HCS 210 Trail, HCS 270 Trail, HSM 230 Trail, FDHSM 230 Trail, HSM 230 Lead and HSM 240 Lead required dilution due to the presence of elevated levels of target analyte. The reporting limits were adjusted to reflect the dilution.

No other anomalies associated with the analysis of these samples were observed.

AMPLIFIED GEOCHEMICAL IMAGING, LLC

Laboratory Report

Site: Comal & San Marcos Rivers
February 2015 Sampling

Prepared for:

SWCA Environmental
10245 Little York Road Suite 600
Houston, Texas
UNITED STATES

Prepared on:
March 04, 2015

Project Summary and Objective

Amplified Geochemical Imaging, LLC. (AGI) provided the AGI Environmental Survey used at:

Comal & San Marcos Rivers

February 2015 Sampling

The service provided by AGI included delivery of the required quantity of AGI Universal Samplers, analysis by the method described below for the requested organic compounds, reporting of the data, and contour mapping (as needed).

This report includes results for only the samples noted under the Laboratory Sample Report section. If contour maps are part of the project deliverable, the maps will be prepared and issued under a separate report cover, upon receipt of a usable sitemap (electronic) and compound choices for contouring.

Written/submitted by:

Jim E Whetzel

Project Manager

Reviewed/approved by:

Don D'Apolito

Project Manager

Analytical data approved by:

Fatima Niazi

Chemist

Quality Assurance Statement

The AGI Laboratory, at Amplified Geochemical Imaging's facility in Elkton, MD USA, operates under the guidelines of its ISO Standard 17025 DoD ELAP accreditation, and its Quality Assurance Manual, Operating Procedures, and Methods (SPG-SOP-0462).

For this project, the analytical method, results, and observations reported do [ ] do not [√] fall within the scope of AGI's ISO 17025 accreditation.

Screening/Concentration Method

The AGI Universal Samplers are analyzed at AGI's fixed laboratory using thermal desorption-gas chromatography/mass spectrometry (TD-GC/MS) instrumentation following U.S. EPA Method 8260 (SPG-WI-0292) which includes the following:

- **BFB Tuning Frequency:** A BFB tune is analyzed at the start of each analytical run and after every 30 samples.
- **Initial Calibration:** A minimum of a five point calibration curve is analyzed prior to the analysis of samples.
- **Linearity of Target Compounds:** If the RSD of any target analyte is less than or equal to 25% then average response factor can be used for quantitation. If the RSD exceeds 25% for a target compound a regression equation can be used for quantitation.
- **Continuing Calibration Verification:** After every 10 samples, and at the end of each analytical batch, and a second-source Reference Standard is analyzed near the mid point of the calibration curve. The acceptance criteria for all target analytes in the reference standards are +/- 50% of the true value.
- **Method Blank:** Analyzed prior to the analysis of field samples and every 30 samples.

Note: Analyte levels reported for the field-deployed AGI Universal Samplers that exceed trip and method blank levels, and/or the reporting limit, are more likely to have originated from on-site sources.

Media Sampled:	WATER
Chemist - sample analysis:	Kelly J Stringham
Chemist - data processor:	Kelly J Stringham
Chemist - data review:	Fatima Niazi

Method deviations: No data is available for the initial method blank. Data was inadvertently overwritten. There was no evidence of system contamination observed in any other QC sample.

Please note that data file names ending with R are rerun samples using the second pair of sorbers, in which the original results were not reported. Data file names ending in D are duplicate analysis results for the second set of sorbers from the same sampler, and are reported.

Additional Report Information

- Comments
- Laboratory Sample Report
- Chain of Custody
- Installation and Retrieval Log
- Analytical Results and Key
- Concentration Calculation Method Summary
- Total Ion Chromatograms

Project Specific Comments

None.

Survey period [1]	Samplers were installed on February 3, 2015 and retrieved on February 17, 2015 for an exposure period of 14 days.
Tamper seal intact:	Yes
Date received:	2/18/2015 1:00 PM By: Lisa Bozette
COC returned:	Yes
Comments:	None

1 - Installation start to end of retrieval, as reported. See installation and retrieval log for individual deployment and retrieval dates and times (i.e., sampler exposure time).

General Comments

Analytical QA/QC

Laboratory instrumentation consists of gas chromatographs equipped with mass selective detectors, coupled with automated thermal desorption units. Sample preparation involves cutting the tip off the bottom of the AGI Universal Sampler, and transferring one or more "sorbers" to a thermal desorption tube for analysis. The insertion/retrieval cord prevents soil, water and other interferences from coming in contact with the adsorbent. No further sample preparation is required. Any replicate sorbers not consumed in the initial analysis will be discarded fifteen (15) days from the date of the laboratory report.

Data are archived and stored in a secure manner as per AGI's Quality Assurance program (SPG-SOP-0462).

Total petroleum hydrocarbons (TPH), gasoline-range petroleum hydrocarbons (GRPH), and/or diesel range petroleum hydrocarbons (DRPH), when reported, are calculated using the area under the peaks observed in m/z 55 and 57 selected ion chromatograms. Quantitation of the mass values was performed using the response factor for a specific alkane (present in the calibration standards). TPH values include the entire chromatogram and provide estimates for aliphatic hydrocarbon ranges of C4 to C20. GRPH and DRPH include only the relevant regions of the chromatograms and provide estimates for C4 to C10 and C10 to C20 aliphatic hydrocarbons, respectively.

Trip blanks were provided to document potential exposures that were not part of the signal of interest (e.g., impact during sampler shipment, installation and/or retrieval, and storage). The trip blanks are identically manufactured and packaged AGI Universal Samplers to those samplers deployed in the field . The trip blanks remain unopened during all phases of the project. Levels reported on the trip blanks may indicate potential impact to the samplers other than the contaminant source of interest.

Unresolved peak envelopes (UPEs) are represented as a series of compound peaks clustered together around a central gas chromatograph elution time in the total ion chromatogram. UPEs may be indicative of complex fluid mixtures. UPEs observed early in the chromatograms are considered to indicate presence of more volatile fluids, while UPEs observed later in the chromatogram may indicate the presence of less volatile fluids. Multiple UPEs may indicate the presence of multiple complex fluids.

Total ion chromatograms (TICs) are included in the Attachments. The eight-digit serial number of each sampler is incorporated in the TIC identification (e.g., 12345678.D represents AGI Universal Sampler 12345678).

General Comments

Soil Gas Sampling

For soil gas sampling, the AGI Environmental Survey reports mass levels migrating through the open pore spaces of the soil and diffusing through the sampler membrane for sorption by the engineered, hydrophobic adsorbents, housed within the membrane tube. During the migration of the soil gas away from the source to the AGI Universal Sampler, the vapors are subject to a variety of attenuation factors. The soil gas masses reported on the samplers compare favorably with the concentrations reported in the soil or groundwater (e.g., where soil gas levels are reported at greater levels to other sampled locations on the site, the matrix data should reveal the same pattern, and vice versa). However, due to a variety of factors, a perfect comparison between matrix data and soil gas levels can rarely be achieved.

Soil gas concentrations (µg/m3) are calculated following the method described in the Additional Report Information section.

Soil gas signals reported by this method cannot be correlated specifically to soil adsorbed, groundwater, and /or free-phase contamination. The soil gas signal reported from each AGI Universal Sampler can evolve from all of these sources. Differentiation between soil and groundwater contamination can only be achieved with prior knowledge of the site history (i.e., the site is known to have groundwater contamination only).

Air Sampling

For indoor, outdoor, and crawlspace air sampling, the AGI Environmental Survey reports mass levels present in the air and diffusing through the sampler membrane for sorption by the engineered adsorbents housed within the membrane tube.

Air concentrations (µg/m3) are calculated following the method described in the Additional Report Information section.

Groundwater and Sediment Porewater Sampling

For groundwater and sediment porewater sampling, the AGI Environmental Survey reports the mass levels of compounds present in the water which, when coming in contact with the sampler membrane, partitions out of solution, and diffuses through the sampler membrane for sorption by the engineered adsorbents.

Water concentrations (µg/L) are calculated using the quantified mass, exposure period and the compound specific uptake rate. The rates were measured under controlled experimental conditions. The uptake rates are corrected for water pressure (depth of the AGI Universal Sampler below the water table), water temperature and the aquifer flow rate. For sediment porewater, the uptake rate is corrected for the reduced volume of water in the sediment, by multiplying the uptake rate by the pore water fraction.

KEY TO DATA TABLE

UNITS

µg	micrograms, relative mass value
µg/m^3	micrograms per cubic meter; estimated soil gas concentration
µg/L	micrograms per Liter; calculated water concentration

DATA QUALIFIERS

>	greater than; value exceeds calibration range, estimated value
<	less than; compound value is below the LOD and RL
J	mass value below LOQ or RL, but above LOD, estimated mass value
E	mass value exceeds upper calibration level, estimated mass value
Q	one or more quality control parameters failed for the compound

ABBREVIATIONS

AVG RL	average reporting limit; calculated based on individual field sample RLs
LOD	limit of detection
LOQ	limit of quantification
MDL	method detection limit
RL	reporting limit

SUMMARY OF SAMPLING RATE CALIBRATION FOR AGI UNIVERSAL SAMPLER IN AQUEOUS PHASES

PURPOSE:

The purpose of this document is to:

1. Summarize the test protocol,
2. Summarize the methodology for analysis of data,
3. Present general results for generating concentration calibration

of the AGI Universal Sampler, part number SPG-0008, in aqueous phase media following AGI's "Standard Practice for Determining the Sampling Rate of Passive Diffusion Samplers in Various Environmental Media": SPG-SOP-0493. The work will be summarized in three parts: Part 1: shallow water, Part 2: deep water, and Part 3: sediment.

Principle of Operation of the AGI Samper

The AGI Universal Sampler is designed with solid adsorbents enclosed inside a tubular microporous PTFE membrane. When placed in water, the pores and hydrophobic nature of the PTFE keep liquid water from entering the membrane until a water head of about 34 feet is reached. The membrane will not keep water vapor from entering but the adsorbents are very hydrophobic and through testing validated to be unaffected by this moisture vapor. In shallow water, <34', volatile and semi-volatile compounds will partition from the dissolved water into the air phase in the PTFE membrane according to Henry's Law. This partitioning is instantaneous and within seconds-minutes, the compound is adsorbed by the adsorbent inside the sealed tube. Because the diffusivity in air is about 10,000 times higher than the diffusivity in water, the sampling rate is controlled by the water contact area of the membrane that allows the Henry's Law effect to occur. This contact area is set by the membrane diameter and length of the sealed tube, which is fixed in AGI's manufacturing process.

Henry's law as well as diffusivity, which are fundamentally incorporated into the sampling rate, are affected by temperature, T, and follow an Arrhenius equation $H_T = Hr \times \exp([-Ea/R](1/Tr - 1/T))$. Because a 5°C temperature change can make a 15% change in sampling rate, the temperature of the sampled water should be known to get the most precise concentration.

The membrane pore size is also small enough that colloidal particles and microbes can not pass through the membrane. This keeps the adsorbent from getting contaminated and eliminates any need to add preservative or chilling during storage or transportation.

When the water pressure exceeds the water entry pressure of the membrane, about 34 feet of water, the water becomes in contact with the solid adsorbent. Under this condition the compounds in the water will partition from the water into the solid. The partitioning coefficient, K_{AW}, can be approximated by the octanol-water coefficient, K_{OW}, but has been measured more precisely in the lab for AGI's specific solid adsorbent. The sampling rate is the product of the sampling rate at <34' of water and the K_{AW}.

In sediment, the sampler measures pore-water concentration, which is generally agreed to be the preferred measurement as it is more indicative of bioavailability. In sediment the volumetric availability of water to the sampler is reduced by the volume fraction solids in the sediment, which typically varies from zero to 35%, but can be has high at 73% in well packed and broad particle size distribution sediments. As a result, sampling rates in sediment are multiplied by the fraction pore water in the sediment to determine concentration.

PART 1: Calibration in shallow water

Part 1 summarizes the work in shallow water generating calibration data, evaluating the physical and chemical factors affecting the sampling rate, and measurement of the actual sampling rates or regression calibration equations needed to determine concentrations.

Sample Generation in water

In this calibration work, solutions of analytes at known concentrations were formulated in clean 4 liter smoked glass jugs by injecting microliter measured amounts of environmental standards using a calibrated syringe into pure or deionized water and stirring for a minimum of 2 hours but generally overnight. Headspace in the jugs was minimized and generally less than 1% by volume during the tests. Jugs were temperature controlled by placing them in a water filled cooler, chilled via a cooper tubing loop in the cooler. Temperature was measured with a certified digital temperature gauge and an average value used for each temperature experiment.

AGI samplers were weighted so they won't float and placed in the jugs at time zero. They were removed at various intervals to generate samples along with duplicates that showed mass increasing with exposure time. The sampler exposure time was selected to span minutes to hours and was generally reduced for high concentration tests to maintain uptake with time in roughly the linear dynamic range. Samplers were removed and dried with a paper towel and returned to their original container for analysis. They were analyzed by AGI's 8260C (SPG-WI-318 or SPG-WI-10028) method in duplicate, which is based on EPA SW846 Method 8260C.

Water samples were also taken and measured at an outside accredited lab using EPA SW846 Method 8260B. The concentrations agreed well with the calculated concentrations based on the standard certification, jug volume, and syringe injection. The variability of the outside lab 8260B values were found to be high, so for the sampling rate calculations we used the concentrations based on syringe dosing.

Calibrations were run at five concentrations, nominally at 6, 24, 118, 590, 1420 ug/L and five temperatures nominally at 5, 10, 15, 20, and 25 degrees centigrade. Samples were taken at 4 different exposure times. Samples were run in duplicate. A total of 176 data points were generated using 28 compounds from AGI's standard compounds list. Tridecane and pentadecane were not evaluated due to their very low solubility in water. In addition, another 23 compounds were tested using an 8260 liquid standard at nominal concentrations of 0.5, 1.0, 5.0, 15, 95, and 470 ug/L at a temperature typical of groundwater, 15°C. This is a living calibration and as additional data are generated, they may be qualified and added to this data set to improve the precision of the sampling rate calibration and broaden the compound list.

Key Variable Effects

As expected from theory, at short to moderate exposure times, mass will increase roughly linearly proportional to exposure time, as well as proportional to concentration, and exponentially with temperature following Arrhenius law. Temperature affects the Henry's law as well as diffusivity in water. Sampling rate is generally independent of concentration and time at mass values significantly below saturation. In the following sections we have characterized the sampling rate for each compound as affected by temperature and also developed calibrations using regression which account for the minor impact of time, and mass.

Concentration using Simple Sampling Rate Determination

A simple way to determine concentration is to measure mass on the AGI sampler, divide by exposure time, and divide by sampling rate, SR.

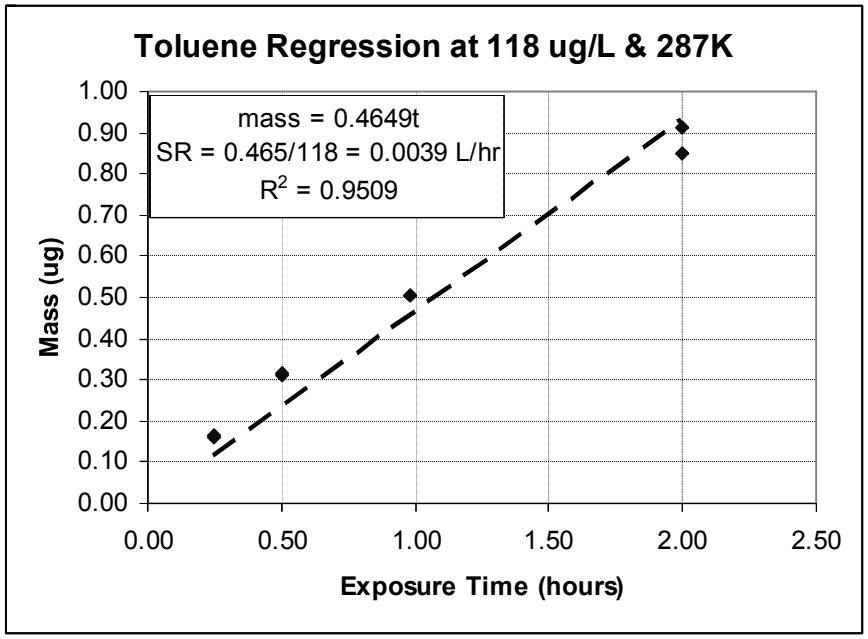
Conc [ug/L] = mass/time/SR (1)

The sampling rate can be determined via measurements of mass versus time at a known concentration and temperature according to the following modification of equation (1).

SR = mass/time/concentration (2)

Sampling rates in L/hr were determined by measuring the trend or regression mass uptake versus time and dividing by the concentration. A measurement like this will use 8 data points (4 times x 2 samples). Such a sampling rate can be measured at any concentration and temperature.

The chart to the right shows a plot of mass versus time for water at 118 ug/L and 287K. This is actual data from a single run. Slope of 0.465 ug/hr divided by the concentration of 118 ug/L yields a sampling rate, SR, of 0.0039 L/hr.



SR's typically range from about 0.004 to 0.007 L/hr at 15°C. Table A shows SR's measured for our standard compound list at 5 temperatures.

Rigorous Concentration using Regression

A preferred method for determining concentration that will yield improved accuracy over a wide range of concentrations, exposure times, and temperatures is to use all data in a regression analysis. This allows adjustments for the minor non-linear influences of mass and time as well as the effects of temperature. This is done by regressing equation (1) or a universal version of equation (1)

$$Conc = (mass)^{b} / (time)^{-d} / [-SRo*exp(-Ea/R/T)] \quad (3)$$

The subtle non-linear effects of mass and time will be evident in the deviation of coefficients b and d from 1.0. This regression generates four constants b, d, SRo, and –Ea/R by regressing ln(conc) versus ln(mass), ln(time), 1/temp. These four constants can be used to determine concentration via the equation:

$$Conc = (mass)^{b} / (time)^{-d} / [-SRo \times exp(-Ea/R(1/T))] \quad (4)$$

Where conc is in ug/L, mass is in ug, time in hours, T in degrees Kelvin.

Equation (4) an be also expressed at a reference temperature, Tr, such as 15°C by

$$Conc = (mass)^{b} / (time)^{-d} / [-SRr \times exp(-Ea/R(1/Tr-1/T))] \quad (5)$$

This allows sampling rates, SRr, at any reference temperature, Tr, and for any analyte to easily be compared. These values of SRr at 293.14K can be found in Table A.

When sampling times are between 0 and 4 hours, using the 4 constant equation (5) is preferred. For concentrations from about 5 to 1500 ug/L one hour exposure times generally give the lowest error, typically with average error of 6-20% and with total error range of 12%-32%. For low concentrations where sampling times are greater than 4 hours, it is preferred to use equation (1) to avoid unrealistic effects from the coefficient d or to set d to 1.0. In such a case SR in equation (1) can be substituted with [SRr x exp(-Ea/R(1/Tr-1/T))] to use an SR representative of the well temperature, T.

The chart to the right is a plot of the calculated concentration from the 4 constant regression compared to the dosed concentration. Agreement is excellent for the 176 data points.

There does appear to be a slight high bias of 8.6% over the full range of this data, although it is well within acceptable limits of variability.

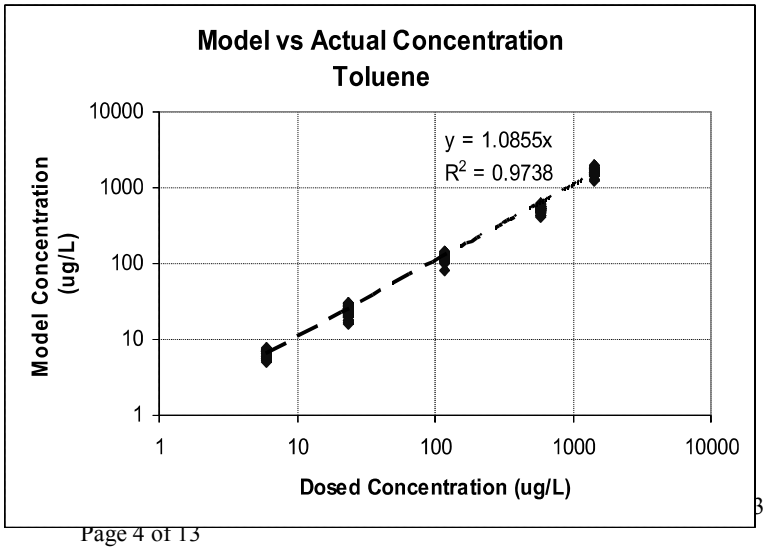


Table B shows the tabulated summary of the 4 constants regression with Rsq values and error estimates for the 4 constants for each analyte. Most regression Rsq values are 0.99 or greater for each analyte. In general, -Ea/R is about 2400+/-400, b is about 0.9, d is about -0.75, and SR(15°C) ranges from .004 L/hr to 0.007 L/hr increasing with MW of the compound.

Error Estimates

The error in the water concentration values will depend on both the error in mass from the analytical method as well as the error in the concentration calibration. Table C shows the error in the mass values from the 8260C low sensitivity method.

The standard error of the regression and standard errors of the constants can be found in table B. For each compound we have measured the error between the derived concentration and the actual concentration. The error tends to be lowest at our recommended exposure time of one hour as shown by the example for Toluene to the right.

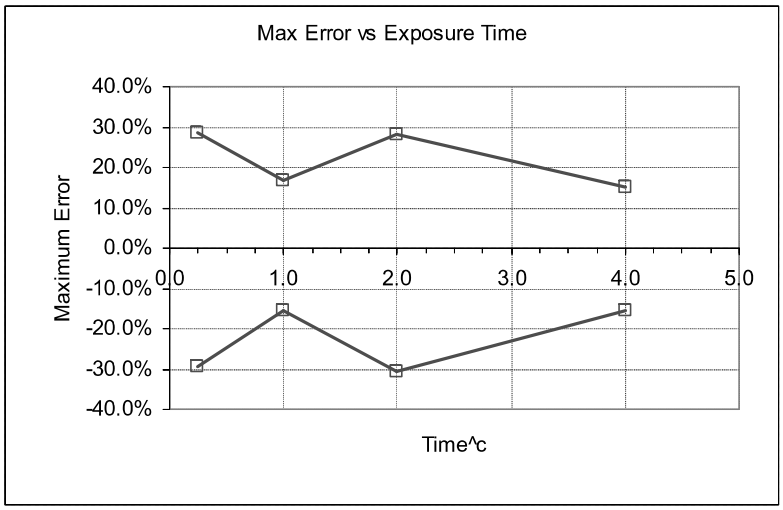

Table D shows the total average error in water concentration by compound as well as the low and high error. The average ranges from about 6% to 20%, which is similar to the analytical method errors. The low and high errors range from 12% to 32% and include contribution from measurement errors in both time and temperature.

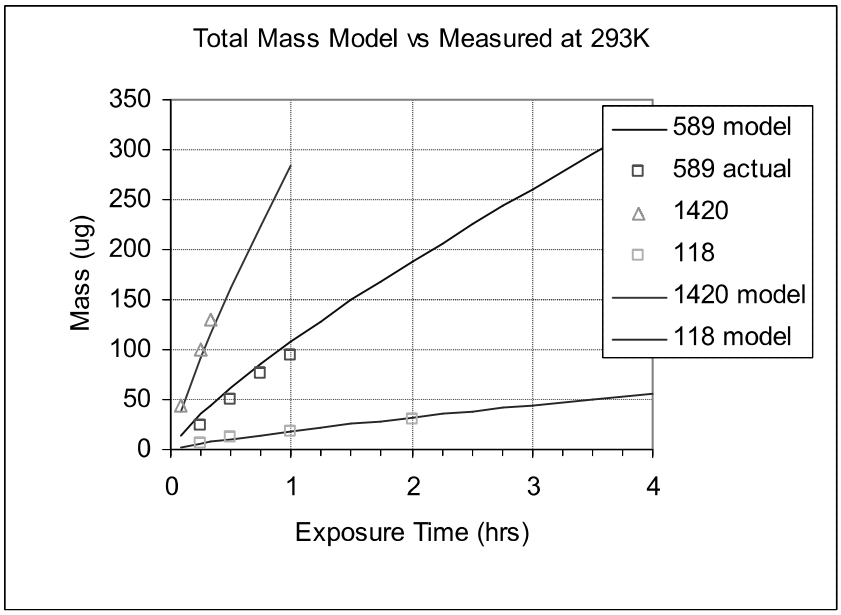
Sorbent Saturation

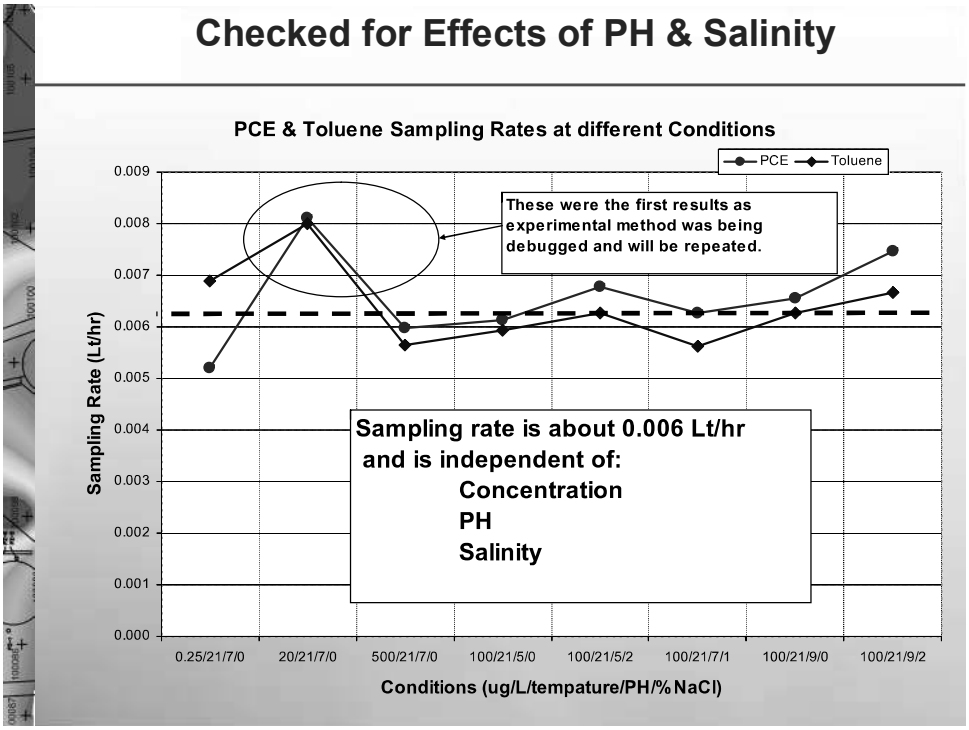
As mass increases on a solid sorbent and approaches saturation, reverse diffusion can occur causing the sampling rate to drop. Eventually the mass level will reach a maximum steady state value at any concentration. A rate of mass uptake with time that deviates significantly from linear, indicates that sorbent saturation could be an issue. When using equation (1), staying in the linear range to avoid the effects of adsorbent saturation is important. We recommend keeping the total mass on the sampler below 50 ug or flagging when this is exceeded.

The 4 constant regression accounts for some of the non linearity allowing good accuracy at higher mass levels. From the experimental data we have found this safe range can be extended to 100 ug or higher as shown in the chart below. This chart compares total mass of all compounds (excluding heavy alkanes, which have solubility issues) versus time in comparison to that predicted from the 4-constant concentration equation.



Effect of PH and Salinity

Because neither PH nor salinity is known to have a significant impact on Henry's law or diffusivity in water, we did not expect them to have a significant impact on sampling rate. To confirm this, experiments were run varying PH from 5 to 9 and NaCl content from 0 to 2%. The chart below shows no significant impact for combinations of PH and NaCl content over this range on the sampling rate of toluene in water at 21°C.

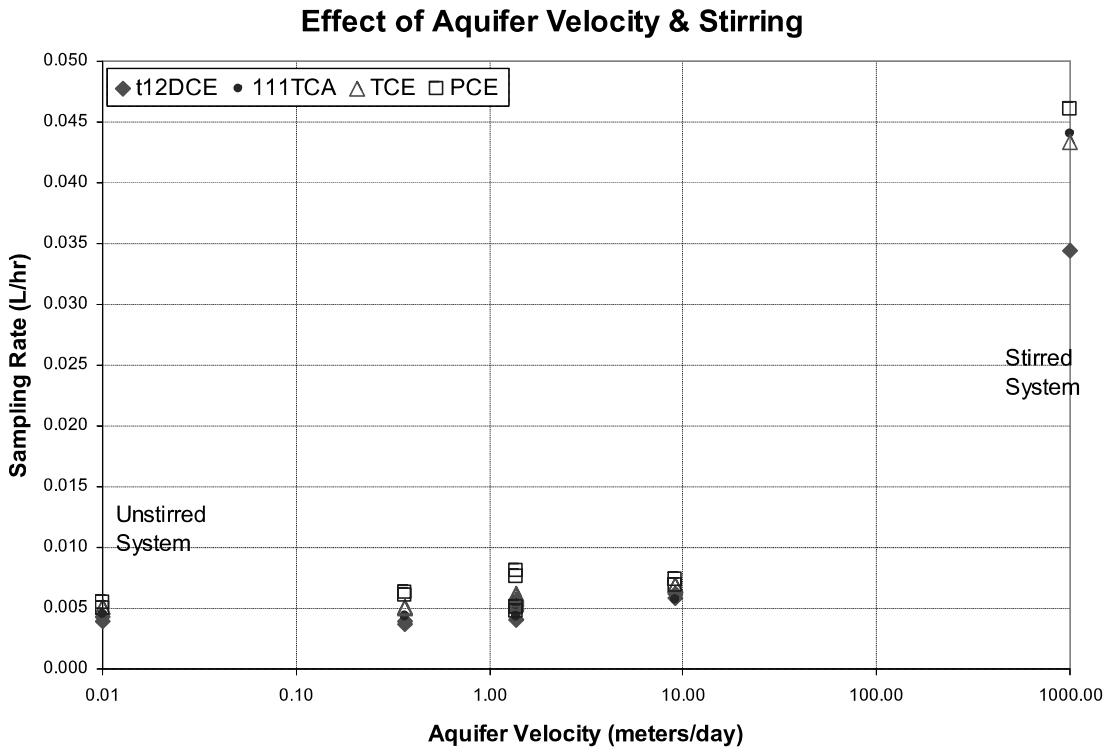


Impact of Aquifer Velocity

The velocity in most aquifers is quite slow, typically a meter/day or less. Occasionally water flow could be much higher such as encountered in karst aquifers, streams or rivers. Mass transfer coefficients are higher in high flow conditions, which will lead to higher sampling rates. We validated that a highly stirred system had sampling rates about 10 times higher than those that were non-stirred. We decided to evaluate the effect of aquifer velocity.

A test apparatus was built comprising a 3" PVC pipe tee filled with clean sand in each of the horizontal straight legs and screened to leave the center open. A test solution was run through this system using a variable flow pump and AGI samplers were placed into the simulated well through the vertical leg of the tee. Tests were run to examine the effect of velocity by varying the pumping rate and hence water velocity.

The chart below shows no significant effect of aquifer velocity up to a speed of about 10 meters/day. At velocities significantly above this, similar to a stirred system, sampling rates are about 10 times higher.

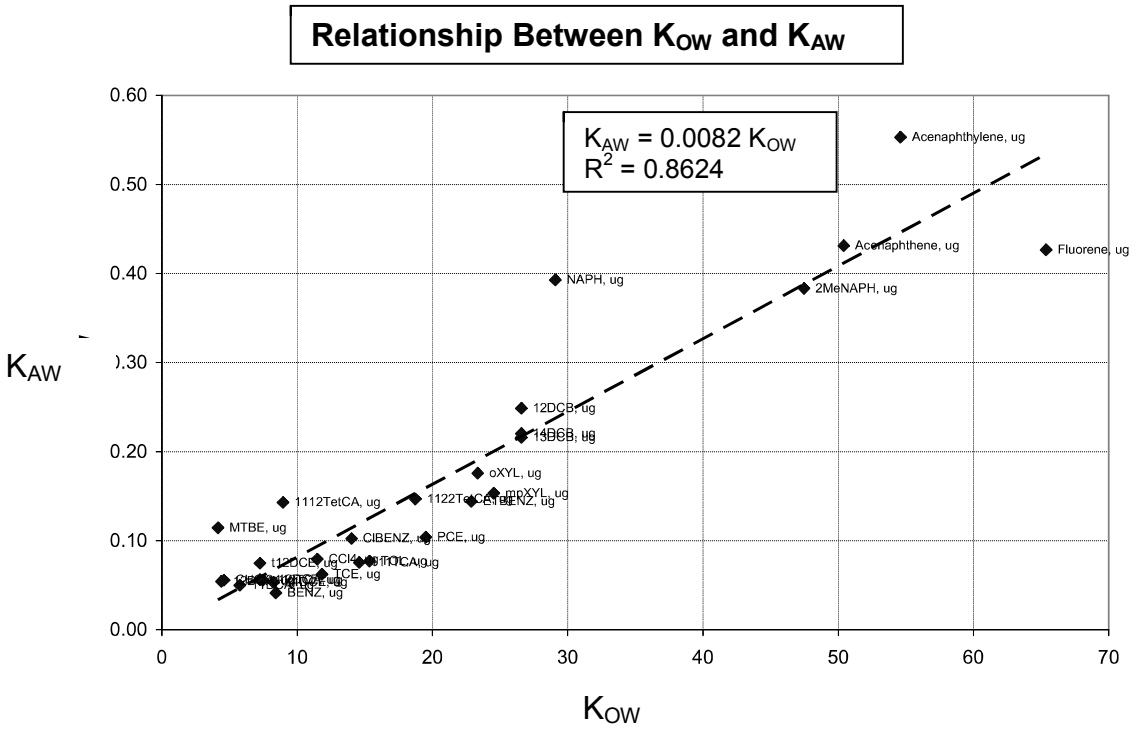


Part 2: Calibration in Deep (>34') water

Part 2 describes the effect of deep water on the AGI sampler and summarizes the effects on sampling rate and concentration measurement.

When the water pressure exceeds the water entry pressure of the membrane, about 34 feet of water, the water becomes in direct contact with the solid adsorbent. Under this condition the compounds in the water will partition from the water into the solid. The portioning coefficient is closely related to the octanol-water coefficient, K_{OW}, but has been measured more precisely in the lab for AGI's specific solid adsorbent, K_{AW}. The sampling rate for deep water is the product of the sampling rate at <34' of water and the K_{AW}.

Measurement of the K_{AW} was done in a one liter stainless steel vessel pressurized with nitrogen to simulate water heads above 34' of water. Pressures of up to 465 psig or 200' of water head were used. The sampling rate change was the same at all pressures above 34' of water. The K_{AW} was determined as the ratio between the mass or sampling rate above 34' of head to the rate at <34' of head and is shown in the chart below.



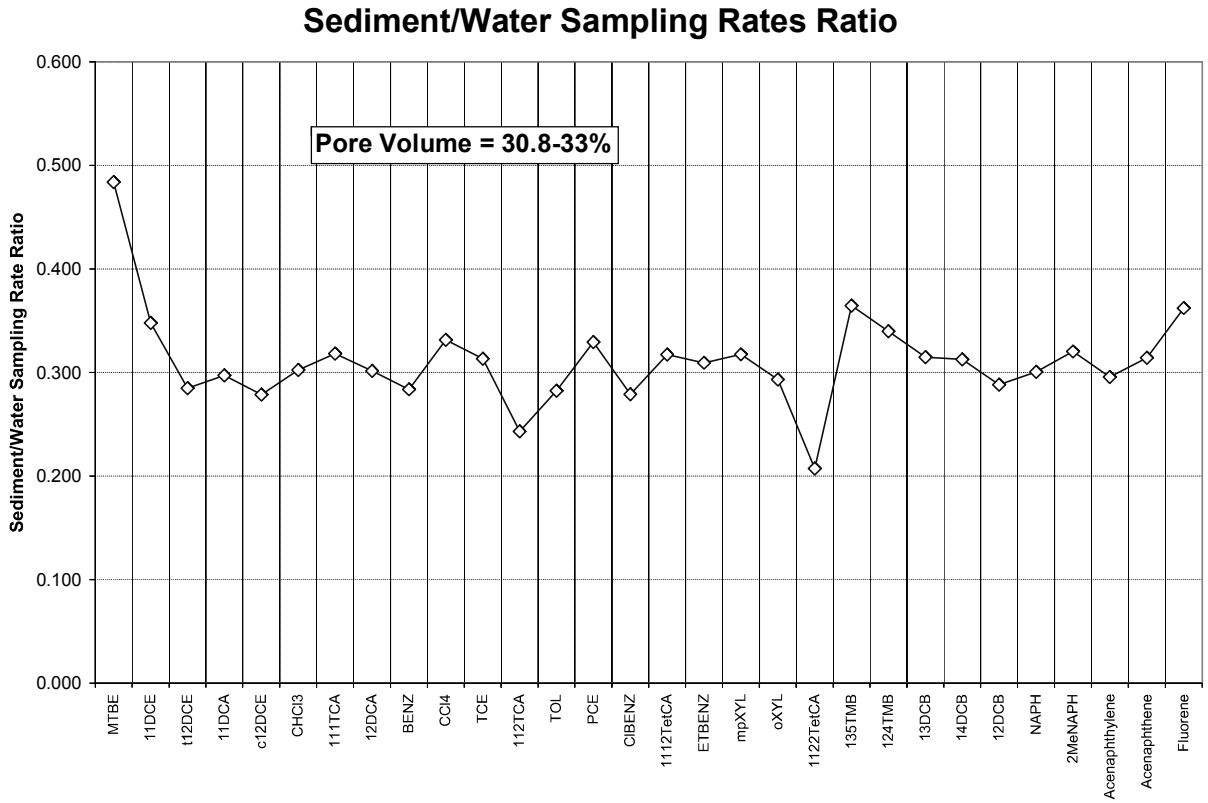
Part 3: Calibration in Sediment

Part 3 describes the effect of sediment solids or sediment pore volume on the sampling rate and concentration measurement.

In sediment, the sampler measures pore water concentration, which is generally agreed to be the preferred measurement as it is more indicative of bioavailability. In sediment the volumetric availability of water to the sampler is reduced by the volume fraction solids in the sediment. As a result sampling rates in sediment are multiplied by the fraction pore water to determine

concentration. Pore water fraction can range from 1.0 for water without sediment to as low as 0.25. Typically most sediments have pore fractions of 0.9 to 0.65.

A sampling rate study was done with water and with water added into a well-packed sorted sand. Pore water fraction in this test was measured between 30.8% 33% by volume. Below is a plot of the ratio of sampling rates measured in the sediment to open water. The average ratio is equal to the pore water fraction confirming that sampling rate in sediment is on average equal to the product of pore water fraction times the sampling rate in water.



Summary

The AGI® Sampler can be used to determine the concentration of volatile and semi-volatile compounds in a water phase. This requires knowing the exposure time and water temperature. It also requires knowing if the sample is above or below 34' of water head and if the water has a velocity above 10 meters/day. Regressions of large amounts of data were used to generate a four constant equation to generate concentration values in water. Potential error in the concentration values is excellent typically less than 25%.

Laboratory Report

Site: Comal and San Marcos Rivers

Prepared for:

SWCA Environmental Consultants
10245 Little York Road Suite 600
San Antonio, TX 77040
UNITED STATES

Prepared on:
May 08, 2015

Project Summary and Objective

Amplified Geochemical Imaging, LLC. (AGI) provided the AGI Environmental Survey used at:

Comal and San Marcos Rivers

The service provided by AGI included delivery of the required quantity of AGI Universal Samplers, analysis by the method described below for the requested organic compounds, reporting of the data, and contour mapping (as needed).

This report includes results for only the samples noted under the Laboratory Sample Report section. If contour maps are part of the project deliverable, the maps will be prepared and issued under a separate report cover, upon receipt of a usable sitemap (electronic) and compound choices for contouring.

Quality Assurance Statement

The AGI Laboratory, at Amplified Geochemical Imaging's facility in Elkton, MD USA, operates under the guidelines of its ISO Standard 17025 DoD ELAP accreditation, and its Quality Assurance Manual, Operating Procedures, and Methods (SPG-SOP-0462).

For this project, the analytical method, results, and observations reported do [ ] do not [√] fall within the scope of AGI's ISO 17025 accreditation.

Screening/Concentration Method

The AGI Universal Samplers are analyzed at AGI's fixed laboratory using thermal desorption-gas chromatography/mass spectrometry (TD-GC/MS) instrumentation following U.S. EPA Method 8260 (SPG-WI-0292) which includes the following:

- **BFB Tuning Frequency:** A BFB tune is analyzed at the start of each analytical run and after every 30 samples.
- **Initial Calibration:** A minimum of a five point calibration curve is analyzed prior to the analysis of samples.
- **Linearity of Target Compounds:** If the RSD of any target analyte is less than or equal to 25% then average response factor can be used for quantitation. If the RSD exceeds 25% for a target compound a regression equation can be used for quantitation.
- **Continuing Calibration Verification:** After every 10 samples, and at the end of each analytical batch, and a second-source Reference Standard is analyzed near the mid point of the calibration curve. The acceptance criteria for all target analytes in the reference standards are +/- 50% of the true value.
- **Method Blank:** Analyzed prior to the analysis of field samples and every 30 samples.

Note: Analyte levels reported for the field-deployed AGI Universal Samplers that exceed trip and method blank levels, and/or the reporting limit, are more likely to have originated from on-site sources.

Media Sampled:	WATER
Chemist - sample analysis:	Kelly J Stringham
Chemist - data processor:	Kelly J Stringham
Chemist - data review:	Jasmine Smith

Method deviations: None.

Please note that data file names ending with R are rerun samples using the second pair of sorbers, in which the original results were not reported. Data file names ending in D are duplicate analysis results for the second set of sorbers from the same sampler, and are reported.

Additional Report Information

- Comments
- Laboratory Sample Report
- Chain of Custody
- Installation and Retrieval Log
- Analytical Results and Key
- Concentration Calculation Method Summary
- Total Ion Chromatograms

Project Specific Comments

None.

Survey period [1]	Samplers were installed on April 7, 2015 and retrieved on April 21, 2015 for an exposure period of 14 days.	
Tamper seal intact:	Yes	
Date received:	4/22/2015 10:25 AM	By: Darlene Yellowdy
COC returned:	Yes	
Comments:	None	

1 - Installation start to end of retrieval, as reported. See installation and retrieval log for individual deployment and retrieval dates and times (i.e., sampler exposure time).

General Comments

Analytical QA/QC

Laboratory instrumentation consists of gas chromatographs equipped with mass selective detectors, coupled with automated thermal desorption units. Sample preparation involves cutting the tip off the bottom of the AGI Universal Sampler, and transferring one or more "sorbers" to a thermal desorption tube for analysis. The insertion/retrieval cord prevents soil, water and other interferences from coming in contact with the adsorbent. No further sample preparation is required. Any replicate sorbers not consumed in the initial analysis will be discarded fifteen (15) days from the date of the laboratory report.

Data are archived and stored in a secure manner as per AGI's Quality Assurance program (SPG-SOP-0462).

Total petroleum hydrocarbons (TPH), gasoline-range petroleum hydrocarbons (GRPH), and/or diesel range petroleum hydrocarbons (DRPH), when reported, are calculated using the area under the peaks observed in m/z 55 and 57 selected ion chromatograms. Quantitation of the mass values was performed using the response factor for a specific alkane (present in the calibration standards). TPH values include the entire chromatogram and provide estimates for aliphatic hydrocarbon ranges of C4 to C20. GRPH and DRPH include only the relevant regions of the chromatograms and provide estimates for C4 to C10 and C10 to C20 aliphatic hydrocarbons, respectively.

Trip blanks were provided to document potential exposures that were not part of the signal of interest (e.g., impact during sampler shipment, installation and/or retrieval, and storage). The trip blanks are identically manufactured and packaged AGI Universal Samplers to those samplers deployed in the field . The trip blanks remain unopened during all phases of the project. Levels reported on the trip blanks may indicate potential impact to the samplers other than the contaminant source of interest.

Unresolved peak envelopes (UPEs) are represented as a series of compound peaks clustered together around a central gas chromatograph elution time in the total ion chromatogram. UPEs may be indicative of complex fluid mixtures. UPEs observed early in the chromatograms are considered to indicate presence of more volatile fluids, while UPEs observed later in the chromatogram may indicate the presence of less volatile fluids. Multiple UPEs may indicate the presence of multiple complex fluids.

Total ion chromatograms (TICs) are included in the Attachments. The eight-digit serial number of each sampler is incorporated in the TIC identification (e.g., 12345678.D represents AGI Universal Sampler 12345678).

General Comments

Soil Gas Sampling

For soil gas sampling, the AGI Environmental Survey reports mass levels migrating through the open pore spaces of the soil and diffusing through the sampler membrane for sorption by the engineered, hydrophobic adsorbents, housed within the membrane tube. During the migration of the soil gas away from the source to the AGI Universal Sampler, the vapors are subject to a variety of attenuation factors. The soil gas masses reported on the samplers compare favorably with the concentrations reported in the soil or groundwater (e.g., where soil gas levels are reported at greater levels to other sampled locations on the site, the matrix data should reveal the same pattern, and vice versa). However, due to a variety of factors, a perfect comparison between matrix data and soil gas levels can rarely be achieved.

Soil gas concentrations (µg/m3) are calculated following the method described in the Additional Report Information section.

Soil gas signals reported by this method cannot be correlated specifically to soil adsorbed, groundwater, and /or free-phase contamination. The soil gas signal reported from each AGI Universal Sampler can evolve from all of these sources. Differentiation between soil and groundwater contamination can only be achieved with prior knowledge of the site history (i.e., the site is known to have groundwater contamination only).

Air Sampling

For indoor, outdoor, and crawlspace air sampling, the AGI Environmental Survey reports mass levels present in the air and diffusing through the sampler membrane for sorption by the engineered adsorbents housed within the membrane tube.

Air concentrations (µg/m3) are calculated following the method described in the Additional Report Information section.

Groundwater and Sediment Porewater Sampling

For groundwater and sediment porewater sampling, the AGI Environmental Survey reports the mass levels of compounds present in the water which, when coming in contact with the sampler membrane, partitions out of solution, and diffuses through the sampler membrane for sorption by the engineered adsorbents.

Water concentrations (µg/L) are calculated using the quantified mass, exposure period and the compound specific uptake rate. The rates were measured under controlled experimental conditions. The uptake rates are corrected for water pressure (depth of the AGI Universal Sampler below the water table), water temperature and the aquifer flow rate. For sediment porewater, the uptake rate is corrected for the reduced colume of water in the sediment, by multiplying the uptake rate by the pore water fraction.

SUMMARY OF SAMPLING RATE CALIBRATION FOR AGI UNIVERSAL SAMPLER IN AQUEOUS PHASES

PURPOSE:

The purpose of this document is to:

1. Summarize the test protocol,
2. Summarize the methodology for analysis of data,
3. Present general results for generating concentration calibration

of the AGI Universal Sampler, part number SPG-0008, in aqueous phase media following AGI's "Standard Practice for Determining the Sampling Rate of Passive Diffusion Samplers in Various Environmental Media": SPG-SOP-0493. The work will be summarized in three parts: Part 1: shallow water, Part 2: deep water, and Part 3: sediment.

Principle of Operation of the AGI Samper

The AGI Universal Sampler is designed with solid adsorbents enclosed inside a tubular microporous PTFE membrane. When placed in water, the pores and hydrophobic nature of the PTFE keep liquid water from entering the membrane until a water head of about 34 feet is reached. The membrane will not keep water vapor from entering but the adsorbents are very hydrophobic and through testing validated to be unaffected by this moisture vapor. In shallow water, <34', volatile and semi-volatile compounds will partition from the dissolved water into the air phase in the PTFE membrane according to Henry's Law. This partitioning is instantaneous and within seconds-minutes, the compound is adsorbed by the adsorbent inside the sealed tube. Because the diffusivity in air is about 10,000 times higher than the diffusivity in water, the sampling rate is controlled by the water contact area of the membrane that allows the Henry's Law effect to occur. This contact area is set by the membrane diameter and length of the sealed tube, which is fixed in AGI's manufacturing process.

Henry's law as well as diffusivity, which are fundamentally incorporated into the sampling rate, are affected by temperature, T, and follow an Arrhenius equation $H_T = Hr \times \exp([-Ea/R](1/Tr - 1/T))$. Because a 5°C temperature change can make a 15% change in sampling rate, the temperature of the sampled water should be known to get the most precise concentration.

The membrane pore size is also small enough that colloidal particles and microbes can not pass through the membrane. This keeps the adsorbent from getting contaminated and eliminates any need to add preservative or chilling during storage or transportation.

When the water pressure exceeds the water entry pressure of the membrane, about 34 feet of water, the water becomes in contact with the solid adsorbent. Under this condition the compounds in the water will partition from the water into the solid. The partitioning coefficient, K_{AW}, can be approximated by the octanol-water coefficient, K_{OW}, but has been measured more precisely in the lab for AGI's specific solid adsorbent. The sampling rate is the product of the sampling rate at <34' of water and the K_{AW}.

In sediment, the sampler measures pore-water concentration, which is generally agreed to be the preferred measurement as it is more indicative of bioavailability. In sediment the volumetric availability of water to the sampler is reduced by the volume fraction solids in the sediment, which typically varies from zero to 35%, but can be has high at 73% in well packed and broad particle size distribution sediments. As a result, sampling rates in sediment are multiplied by the fraction pore water in the sediment to determine concentration.

PART 1: Calibration in shallow water

Part 1 summarizes the work in shallow water generating calibration data, evaluating the physical and chemical factors affecting the sampling rate, and measurement of the actual sampling rates or regression calibration equations needed to determine concentrations.

Sample Generation in water

In this calibration work, solutions of analytes at known concentrations were formulated in clean 4 liter smoked glass jugs by injecting microliter measured amounts of environmental standards using a calibrated syringe into pure or deionized water and stirring for a minimum of 2 hours but generally overnight. Headspace in the jugs was minimized and generally less than 1% by volume during the tests. Jugs were temperature controlled by placing them in a water filled cooler, chilled via a cooper tubing loop in the cooler. Temperature was measured with a certified digital temperature gauge and an average value used for each temperature experiment.

AGI samplers were weighted so they won't float and placed in the jugs at time zero. They were removed at various intervals to generate samples along with duplicates that showed mass increasing with exposure time. The sampler exposure time was selected to span minutes to hours and was generally reduced for high concentration tests to maintain uptake with time in roughly the linear dynamic range. Samplers were removed and dried with a paper towel and returned to their original container for analysis. They were analyzed by AGI's 8260C (SPG-WI-318 or SPG-WI-10028) method in duplicate, which is based on EPA SW846 Method 8260C.

Water samples were also taken and measured at an outside accredited lab using EPA SW846 Method 8260B. The concentrations agreed well with the calculated concentrations based on the standard certification, jug volume, and syringe injection. The variability of the outside lab 8260B values were found to be high, so for the sampling rate calculations we used the concentrations based on syringe dosing.

Calibrations were run at five concentrations, nominally at 6, 24, 118, 590, 1420 ug/L and five temperatures nominally at 5, 10, 15, 20, and 25 degrees centigrade. Samples were taken at 4 different exposure times. Samples were run in duplicate. A total of 176 data points were generated using 28 compounds from AGI's standard compounds list. Tridecane and pentadecane were not evaluated due to their very low solubility in water. In addition, another 23 compounds were tested using an 8260 liquid standard at nominal concentrations of 0.5, 1.0, 5.0, 15, 95, and 470 ug/L at a temperature typical of groundwater, 15°C. This is a living calibration and as additional data are generated, they may be qualified and added to this data set to improve the precision of the sampling rate calibration and broaden the compound list.

Key Variable Effects

As expected from theory, at short to moderate exposure times, mass will increase roughly linearly proportional to exposure time, as well as proportional to concentration, and exponentially with temperature following Arrhenius law. Temperature affects the Henry's law as well as diffusivity in water. Sampling rate is generally independent of concentration and time at mass values significantly below saturation. In the following sections we have characterized the sampling rate for each compound as affected by temperature and also developed calibrations using regression which account for the minor impact of time, and mass.

Concentration using Simple Sampling Rate Determination

A simple way to determine concentration is to measure mass on the AGI sampler, divide by exposure time, and divide by sampling rate, SR.

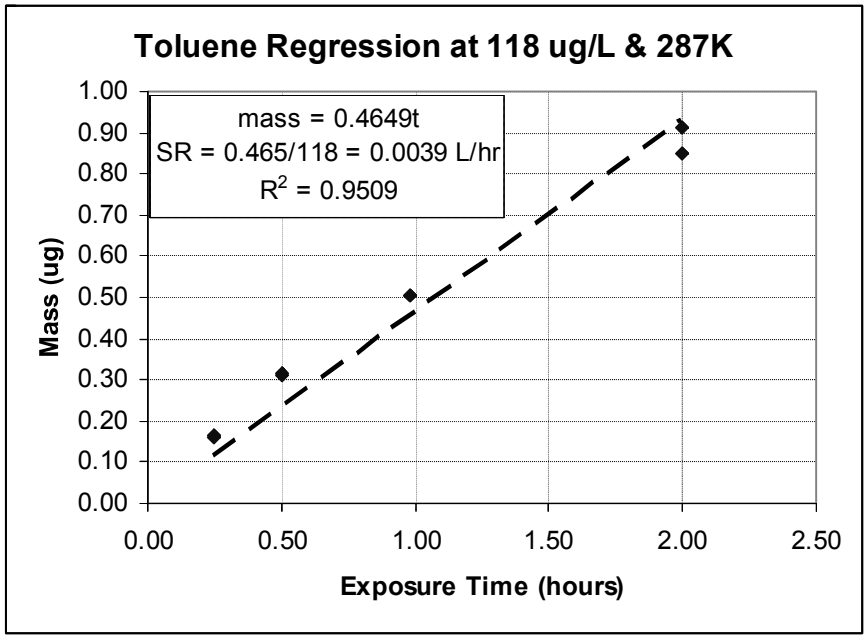
Conc [ug/L] = mass/time/SR (1)

The sampling rate can be determined via measurements of mass versus time at a known concentration and temperature according to the following modification of equation (1).

SR = mass/time/concentration (2)

Sampling rates in L/hr were determined by measuring the trend or regression mass uptake versus time and dividing by the concentration. A measurement like this will use 8 data points (4 times x 2 samples). Such a sampling rate can be measured at any concentration and temperature.

The chart to the right shows a plot of mass versus time for water at 118 ug/L and 287K. This is actual data from a single run. Slope of 0.465 ug/hr divided by the concentration of 118 ug/L yields a sampling rate, SR, of 0.0039 L/hr.



SR's typically range from about 0.004 to 0.007 L/hr at 15°C. Table A shows SR's measured for our standard compound list at 5 temperatures.

Rigorous Concentration using Regression

A preferred method for determining concentration that will yield improved accuracy over a wide range of concentrations, exposure times, and temperatures is to use all data in a regression analysis. This allows adjustments for the minor non-linear influences of mass and time as well as the effects of temperature. This is done by regressing equation (1) or a universal version of equation (1)

$$Conc = (mass)^{b} / (time)^{-d} / [-SRo*exp(-Ea/R/T)] \quad (3)$$

The subtle non-linear effects of mass and time will be evident in the deviation of coefficients b and d from 1.0. This regression generates four constants b, d, SRo, and –Ea/R by regressing ln(conc) versus ln(mass), ln(time), 1/temp. These four constants can be used to determine concentration via the equation:

$$Conc = (mass)^{b} / (time)^{-d} / [-SRo \times exp(-Ea/R(1/T))] \quad (4)$$

Where conc is in ug/L, mass is in ug, time in hours, T in degrees Kelvin.

Equation (4) an be also expressed at a reference temperature, Tr, such as 15°C by

$$Conc = (mass)^{b} / (time)^{-d} / [-SRr \times exp(-Ea/R(1/Tr-1/T))] \quad (5)$$

This allows sampling rates, SRr, at any reference temperature, Tr, and for any analyte to easily be compared. These values of SRr at 293.14K can be found in Table A.

When sampling times are between 0 and 4 hours, using the 4 constant equation (5) is preferred. For concentrations from about 5 to 1500 ug/L one hour exposure times generally give the lowest error, typically with average error of 6-20% and with total error range of 12%-32%. For low concentrations where sampling times are greater than 4 hours, it is preferred to use equation (1) to avoid unrealistic effects from the coefficient d or to set d to 1.0. In such a case SR in equation (1) can be substituted with [SRr x exp(-Ea/R(1/Tr-1/T))] to use an SR representative of the well temperature, T.

The chart to the right is a plot of the calculated concentration from the 4 constant regression compared to the dosed concentration. Agreement is excellent for the 176 data points.

There does appear to be a slight high bias of 8.6% over the full range of this data, although it is well within acceptable limits of variability.

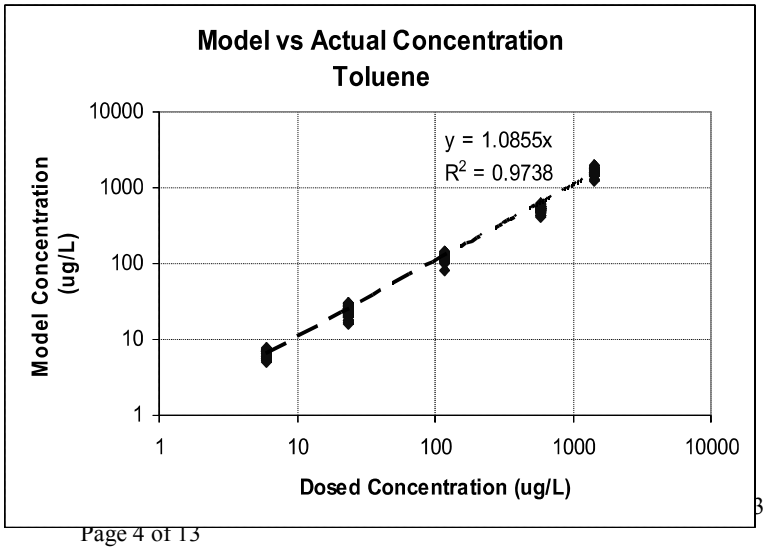


Table B shows the tabulated summary of the 4 constants regression with Rsq values and error estimates for the 4 constants for each analyte. Most regression Rsq values are 0.99 or greater for each analyte. In general, -Ea/R is about 2400+/-400, b is about 0.9, d is about -0.75, and SR(15°C) ranges from .004 L/hr to 0.007 L/hr increasing with MW of the compound.

Error Estimates

The error in the water concentration values will depend on both the error in mass from the analytical method as well as the error in the concentration calibration. Table C shows the error in the mass values from the 8260C low sensitivity method.

The standard error of the regression and standard errors of the constants can be found in table B. For each compound we have measured the error between the derived concentration and the actual concentration. The error tends to be lowest at our recommended exposure time of one hour as shown by the example for Toluene to the right.

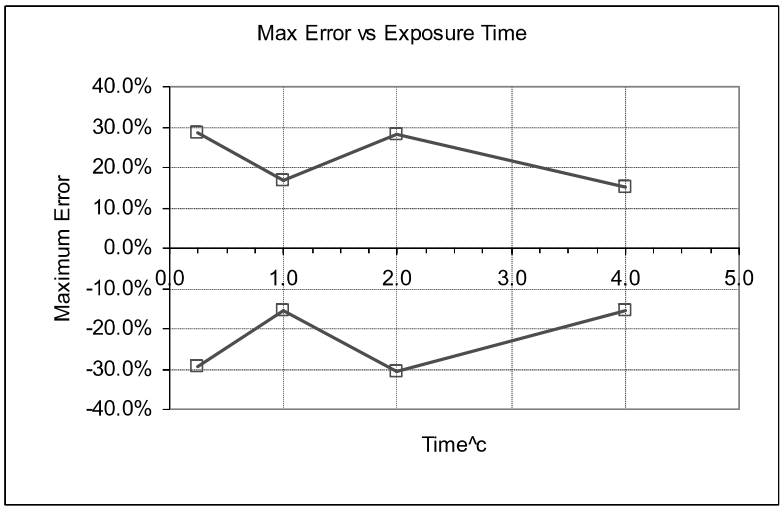

Table D shows the total average error in water concentration by compound as well as the low and high error. The average ranges from about 6% to 20%, which is similar to the analytical method errors. The low and high errors range from 12% to 32% and include contribution from measurement errors in both time and temperature.

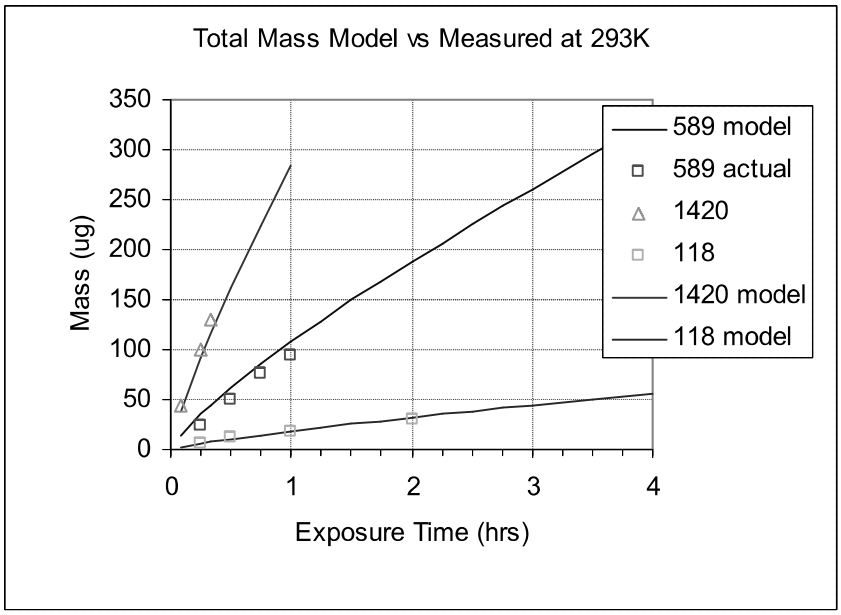
Sorbent Saturation

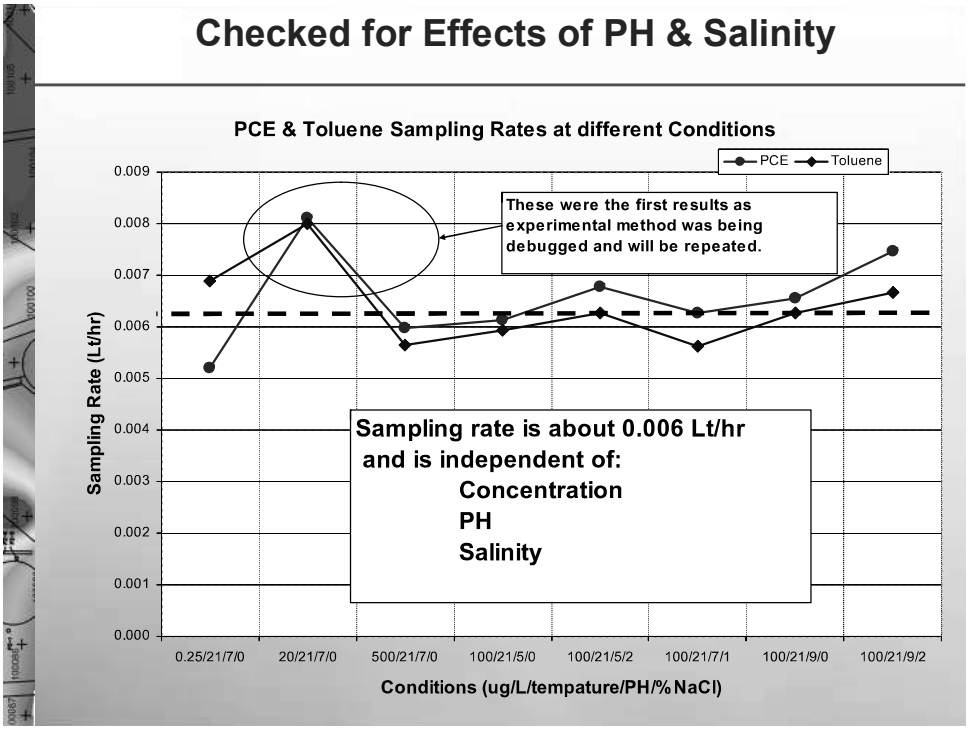
As mass increases on a solid sorbent and approaches saturation, reverse diffusion can occur causing the sampling rate to drop. Eventually the mass level will reach a maximum steady state value at any concentration. A rate of mass uptake with time that deviates significantly from linear, indicates that sorbent saturation could be an issue. When using equation (1), staying in the linear range to avoid the effects of adsorbent saturation is important. We recommend keeping the total mass on the sampler below 50 ug or flagging when this is exceeded.

The 4 constant regression accounts for some of the non linearity allowing good accuracy at higher mass levels. From the experimental data we have found this safe range can be extended to 100 ug or higher as shown in the chart below. This chart compares total mass of all compounds (excluding heavy alkanes, which have solubility issues) versus time in comparison to that predicted from the 4-constant concentration equation.



Effect of PH and Salinity

Because neither PH nor salinity is known to have a significant impact on Henry's law or diffusivity in water, we did not expect them to have a significant impact on sampling rate. To confirm this, experiments were run varying PH from 5 to 9 and NaCl content from 0 to 2%. The chart below shows no significant impact for combinations of PH and NaCl content over this range on the sampling rate of toluene in water at 21°C.

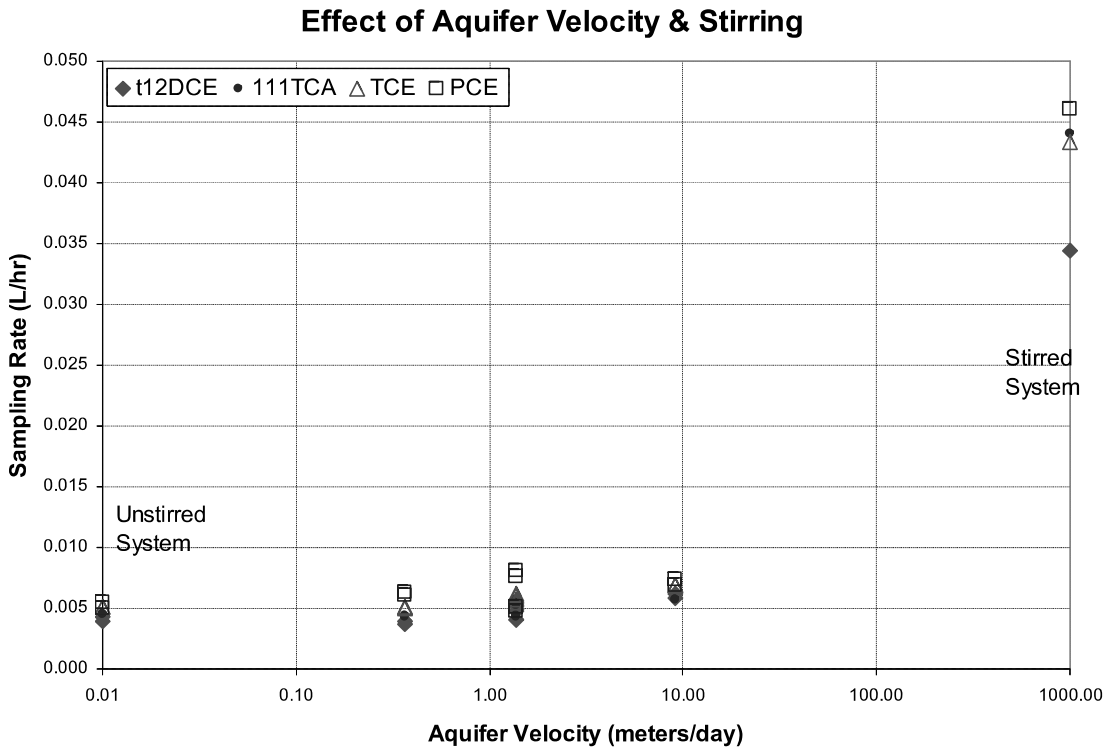


Impact of Aquifer Velocity

The velocity in most aquifers is quite slow, typically a meter/day or less. Occasionally water flow could be much higher such as encountered in karst aquifers, streams or rivers. Mass transfer coefficients are higher in high flow conditions, which will lead to higher sampling rates. We validated that a highly stirred system had sampling rates about 10 times higher than those that were non-stirred. We decided to evaluate the effect of aquifer velocity.

A test apparatus was built comprising a 3" PVC pipe tee filled with clean sand in each of the horizontal straight legs and screened to leave the center open. A test solution was run through this system using a variable flow pump and AGI samplers were placed into the simulated well through the vertical leg of the tee. Tests were run to examine the effect of velocity by varying the pumping rate and hence water velocity.

The chart below shows no significant effect of aquifer velocity up to a speed of about 10 meters/day. At velocities significantly above this, similar to a stirred system, sampling rates are about 10 times higher.

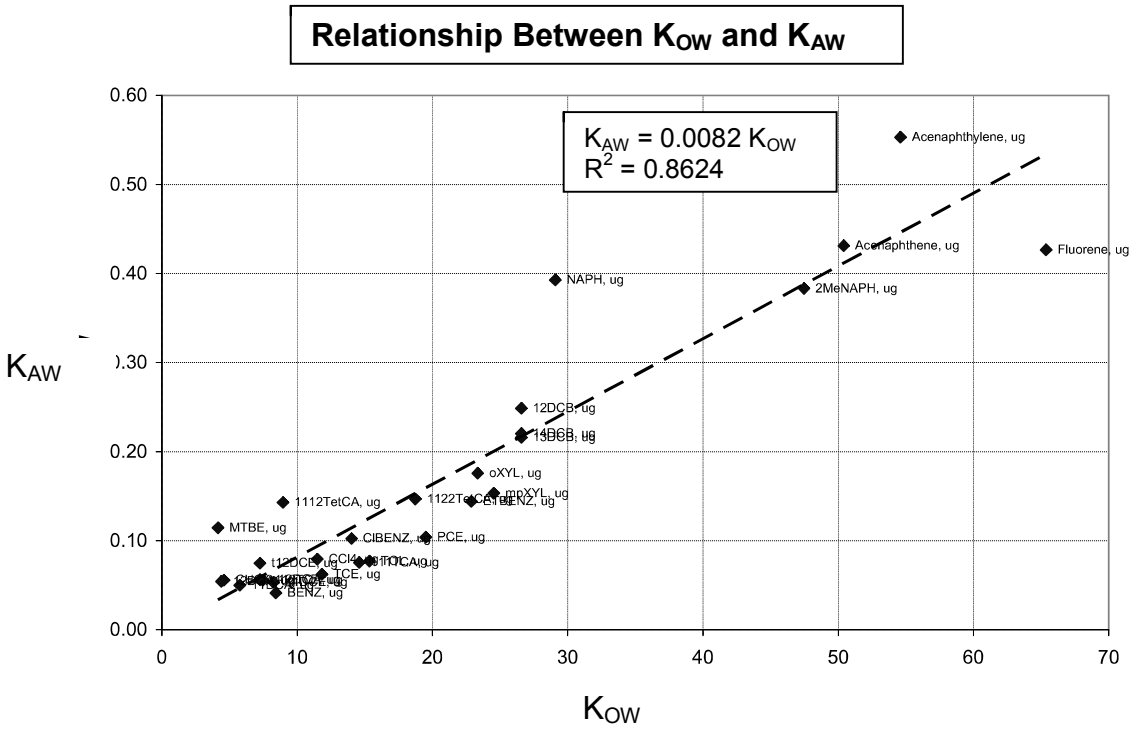


Part 2: Calibration in Deep (>34') water

Part 2 describes the effect of deep water on the AGI sampler and summarizes the effects on sampling rate and concentration measurement.

When the water pressure exceeds the water entry pressure of the membrane, about 34 feet of water, the water becomes in direct contact with the solid adsorbent. Under this condition the compounds in the water will partition from the water into the solid. The portioning coefficient is closely related to the octanol-water coefficient, K_{OW}, but has been measured more precisely in the lab for AGI's specific solid adsorbent, K_{AW}. The sampling rate for deep water is the product of the sampling rate at <34' of water and the K_{AW}.

Measurement of the K_{AW} was done in a one liter stainless steel vessel pressurized with nitrogen to simulate water heads above 34' of water. Pressures of up to 465 psig or 200' of water head were used. The sampling rate change was the same at all pressures above 34' of water. The K_{AW} was determined as the ratio between the mass or sampling rate above 34' of head to the rate at <34' of head and is shown in the chart below.



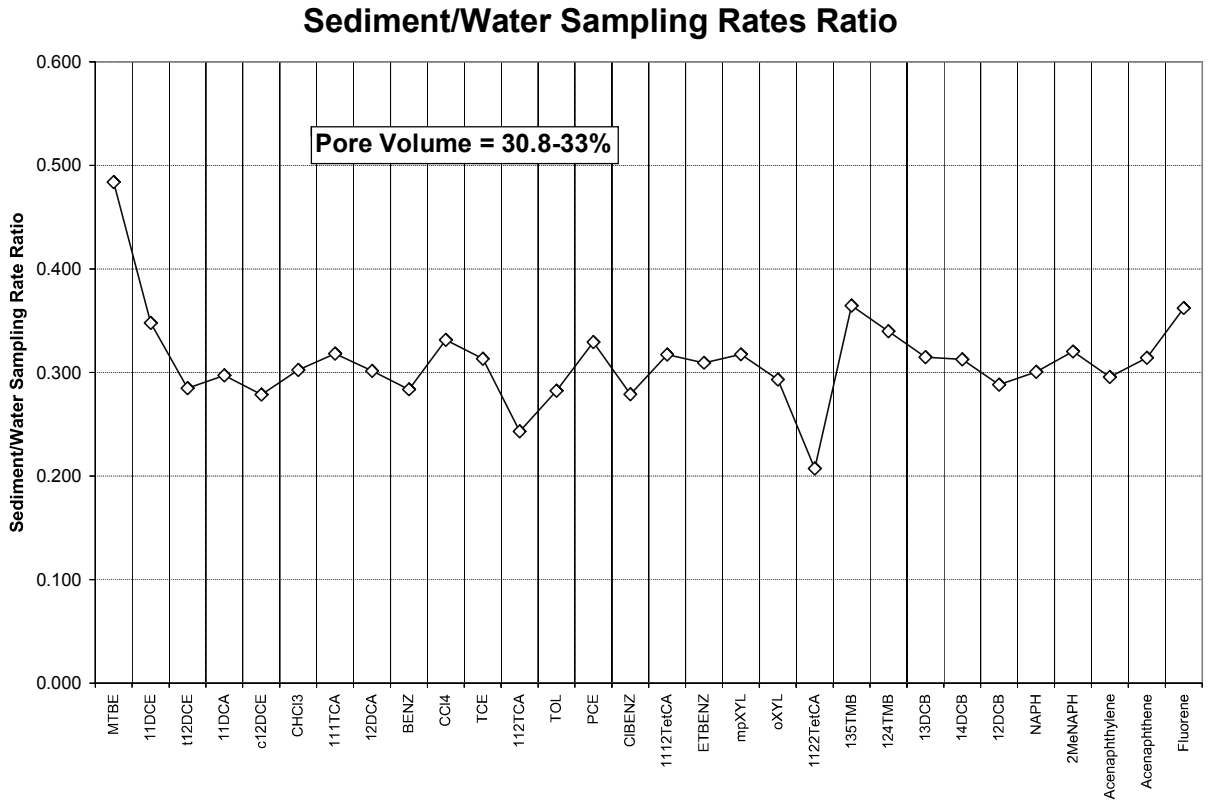
Part 3: Calibration in Sediment

Part 3 describes the effect of sediment solids or sediment pore volume on the sampling rate and concentration measurement.

In sediment, the sampler measures pore water concentration, which is generally agreed to be the preferred measurement as it is more indicative of bioavailability. In sediment the volumetric availability of water to the sampler is reduced by the volume fraction solids in the sediment. As a result sampling rates in sediment are multiplied by the fraction pore water to determine

concentration. Pore water fraction can range from 1.0 for water without sediment to as low as 0.25. Typically most sediments have pore fractions of 0.9 to 0.65.

A sampling rate study was done with water and with water added into a well-packed sorted sand. Pore water fraction in this test was measured between 30.8% 33% by volume. Below is a plot of the ratio of sampling rates measured in the sediment to open water. The average ratio is equal to the pore water fraction confirming that sampling rate in sediment is on average equal to the product of pore water fraction times the sampling rate in water.



Summary

The AGI® Sampler can be used to determine the concentration of volatile and semi-volatile compounds in a water phase. This requires knowing the exposure time and water temperature. It also requires knowing if the sample is above or below 34' of water head and if the water has a velocity above 10 meters/day. Regressions of large amounts of data were used to generate a four constant equation to generate concentration values in water. Potential error in the concentration values is excellent typically less than 25%.

AMPLIFIED GEOCHEMICAL IMAGING, LLC

Laboratory Report

Site: Comal and San Marcos Rivers

Prepared for:

SWCA Environmental Consultants
6200 UTSA Boulevard
Suite 102
San Antonio, TX
UNITED STATES

Prepared on:
July 02, 2015

Project Summary and Objective

Amplified Geochemical Imaging, LLC. (AGI) provided the AGI Environmental Survey used at:

Comal and San Marcos Rivers

The service provided by AGI included delivery of the required quantity of AGI Universal Samplers, analysis by the method described below for the requested organic compounds, reporting of the data, and contour mapping (as needed).

This report includes results for only the samples noted under the Laboratory Sample Report section. If contour maps are part of the project deliverable, the maps will be prepared and issued under a separate report cover, upon receipt of a usable sitemap (electronic) and compound choices for contouring.

Quality Assurance Statement

The AGI Laboratory, at Amplified Geochemical Imaging's facility in Elkton, MD USA, operates under the guidelines of its ISO Standard 17025 DoD ELAP accreditation, and its Quality Assurance Manual, Operating Procedures, and Methods (SPG-SOP-0462).

For this project, the analytical method, results, and observations reported do [ ] do not [√] fall within the scope of AGI's ISO 17025 accreditation.

Screening/Concentration Method

The AGI Universal Samplers are analyzed at AGI's fixed laboratory using thermal desorption-gas chromatography/mass spectrometry (TD-GC/MS) instrumentation following U.S. EPA Method 8260 (SPG-WI-0292) which includes the following:

- **BFB Tuning Frequency:** A BFB tune is analyzed at the start of each analytical run and after every 30 samples.
- **Initial Calibration:** A minimum of a five point calibration curve is analyzed prior to the analysis of samples.
- **Linearity of Target Compounds:** If the RSD of any target analyte is less than or equal to 25% then average response factor can be used for quantitation. If the RSD exceeds 25% for a target compound a regression equation can be used for quantitation.
- **Continuing Calibration Verification:** After every 10 samples, and at the end of each analytical batch, and a second-source Reference Standard is analyzed near the mid point of the calibration curve. The acceptance criteria for all target analytes in the reference standards are +/- 50% of the true value.
- **Method Blank:** Analyzed prior to the analysis of field samples and every 30 samples.

Note: Analyte levels reported for the field-deployed AGI Universal Samplers that exceed trip and method blank levels, and/or the reporting limit, are more likely to have originated from on-site sources.

Media Sampled:	WATER
Chemist - sample analysis:	Kelly J Stringham
Chemist - data processor:	Fatima Niazi
Chemist - data review:	Jasmine Smith

Method deviations: None.

Please note that data file names ending with R are rerun samples using the second pair of sorbers, in which the original results were not reported. Data file names ending in D are duplicate analysis results for the second set of sorbers from the same sampler, and are reported.

Additional Report Information

- Comments
- Laboratory Sample Report
- Chain of Custody
- Installation and Retrieval Log
- Analytical Results and Key
- Concentration Calculation Method Summary (as applicable)
- Total Ion Chromatograms

Project Specific Comments

In addition to AGI's standard VOC/ SVOC target compounds pesticides and additional PAH compounds were included in the target compound list. These additional compounds were quantified using a single level calibration standard. Analytical results for these additional compounds were reported only in relative mass values.

Survey period [1]	Samplers were installed on June 1, 2015 and retrieved on June 15, 2015 for an exposure period of 14 days.
Tamper seal intact:	Yes
Date received:	6/18/2015 10:30 AM By: Clarence W Whigham
COC returned:	Yes

Comments:

Upon retrieval several samples were placed in incorrect sample vials. New labels were placed on vials to indicate actual sample.
Sample 759950 was returned loose in the box. Sample was noted as a trip blank on the installation log, but not on chain of custody. Samples was not analyzed.

1 - Installation start to end of retrieval, as reported. See installation and retrieval log for individual deployment and retrieval dates and times (i.e., sampler exposure time).

General Comments

Analytical QA/QC

Laboratory instrumentation consists of gas chromatographs equipped with mass selective detectors, coupled with automated thermal desorption units. Sample preparation involves cutting the tip off the bottom of the AGI Universal Sampler, and transferring one or more "sorbers" to a thermal desorption tube for analysis. The insertion/retrieval cord prevents soil, water and other interferences from coming in contact with the adsorbent. No further sample preparation is required. Any replicate sorbers not consumed in the initial analysis will be discarded fifteen (15) days from the date of the laboratory report.

Data are archived and stored in a secure manner as per AGI's Quality Assurance program (SPG-SOP-0462).

Total petroleum hydrocarbons (TPH), gasoline-range petroleum hydrocarbons (GRPH), and/or diesel range petroleum hydrocarbons (DRPH), when reported, are calculated using the area under the peaks observed in m/z 55 and 57 selected ion chromatograms. Quantitation of the mass values was performed using the response factor for a specific alkane (present in the calibration standards). TPH values include the entire chromatogram and provide estimates for aliphatic hydrocarbon ranges of C4 to C20. GRPH and DRPH include only the relevant regions of the chromatograms and provide estimates for C4 to C10 and C10 to C20 aliphatic hydrocarbons, respectively.

Trip blanks were provided to document potential exposures that were not part of the signal of interest (e.g., impact during sampler shipment, installation and/or retrieval, and storage). The trip blanks are identically manufactured and packaged AGI Universal Samplers to those samplers deployed in the field . The trip blanks remain unopened during all phases of the project. Levels reported on the trip blanks may indicate potential impact to the samplers other than the contaminant source of interest.

Unresolved peak envelopes (UPEs) are represented as a series of compound peaks clustered together around a central gas chromatograph elution time in the total ion chromatogram. UPEs may be indicative of complex fluid mixtures. UPEs observed early in the chromatograms are considered to indicate presence of more volatile fluids, while UPEs observed later in the chromatogram may indicate the presence of less volatile fluids. Multiple UPEs may indicate the presence of multiple complex fluids.

Total ion chromatograms (TICs) are included in the Attachments. The eight-digit serial number of each sampler is incorporated in the TIC identification (e.g., 12345678.D represents AGI Universal Sampler 12345678).

Soil Gas Sampling

For soil gas sampling, the AGI Environmental Survey reports mass levels migrating through the open pore spaces of the soil and diffusing through the sampler membrane for sorption by the engineered, hydrophobic adsorbents, housed within the membrane tube. During the migration of the soil gas away from the source to the AGI Universal Sampler, the vapors are subject to a variety of attenuation factors. The soil gas masses reported on the samplers compare favorably with the concentrations reported in the soil or groundwater (e.g., where soil gas levels are reported at greater levels to other sampled locations on the site, the matrix data should reveal the same pattern, and vice versa). However, due to a variety of factors, a perfect comparison between matrix data and soil gas levels can rarely be achieved.

Soil gas concentrations (µg/m3) are calculated following the method described in the Additional Report Information section.

Soil gas signals reported by this method cannot be correlated specifically to soil adsorbed, groundwater, and /or free-phase contamination. The soil gas signal reported from each AGI Universal Sampler can evolve from all of these sources. Differentiation between soil and groundwater contamination can only be achieved with prior knowledge of the site history (i.e., the site is known to have groundwater contamination only).

Air Sampling

For indoor, outdoor, and crawlspace air sampling, the AGI Environmental Survey reports mass levels present in the air and diffusing through the sampler membrane for sorption by the engineered adsorbents housed within the membrane tube.

Air concentrations (µg/m3) are calculated following the method described in the Additional Report Information section.

Groundwater and Sediment Porewater Sampling

For groundwater and sediment porewater sampling, the AGI Environmental Survey reports the mass levels of compounds present in the water which, when coming in contact with the sampler membrane, partitions out of solution, and diffuses through the sampler membrane for sorption by the engineered adsorbents.

Water concentrations (µg/L) are calculated using the quantified mass, exposure period and the compound specific uptake rate. The rates were measured under controlled experimental conditions. The uptake rates are corrected for water pressure (depth of the AGI Universal Sampler below the water table), water temperature and the aquifer flow rate. For sediment porewater, the uptake rate is corrected for the reduced colume of water in the sediment, by multiplying the uptake rate by the pore water fraction.

LABORATORY SAMPLE REPORT

Project: ENV 01387 **Site Name: Comal and San Marcos Rivers** **Module Type: SPG0008**

Module ID	Sample Type	Field ID
00759935	FIELD_SAMPLE	HCS430
00759936	FIELD_SAMPLE	HCS410
00759937	FIELD_SAMPLE	HCS420
00759938	FIELD_SAMPLE	HCS440

Project Manager:

Serial # of Samplers Shipped
00759935 - 00759950

# of Samplers for Installation 14.00
Total Samplers Shipped 16.00
Total Samplers Received 16
Total Samplers Installed 14

# of Trip Blanks 2
Pieces
Pieces
Pieces

Vial for 00759947 lost in field, Used vial from extra sampler #00759950

00759950 enclosed in box ~~out~~ loose, not in a vial

Serial # of Trip Blanks (Client Decides)

00759949		

Prepared By: [signature]

Verified By: Lisa Bozzette

Is Concurrent water sampling planned this monitoring period? YES (NO)

Scheduled Sampling Date:

Installation Performed By:
Name: Jennifer Moreland / Brittany Rios
Company: SWCA

Installation Start Date / Time: 6/1/15 1036
Installation Complete Date / Time 6/1/15 1559

Retrieval Performed By:
Name: Jennifer Moreland / Brittany Rios
Company: SWCA

Retrieval Start Date / Time: 6/15/15 10:26
Retrieval Complete Date / Time 6/15/15 14:01

Total Samplers Retrieved: 14
Total Samplers Lost In Field: 0
Total Unused Samplers Returned: 1

KEY TO DATA TABLE

UNITS

µg	micrograms, relative mass value
µg/m^3	micrograms per cubic meter; estimated soil gas concentration
µg/L	micrograms per Liter; calculated water concentration

DATA QUALIFIERS

>	greater than; value exceeds calibration range, estimated value
<	less than; compound value is below the LOD and RL
J	mass value below LOQ or RL, but above LOD, estimated mass value
E	mass value exceeds upper calibration level, estimated mass value
Q	one or more quality control parameters failed for the compound

ABBREVIATIONS

AVG RL	average reporting limit; calculated based on individual field sample RLs
LOD	limit of detection
LOQ	limit of quantification
MDL	method detection limit
RL	reporting limit

1112TetCA	1,1,1,2-tetrachloroethane
111TCA	1,1,1-trichloroethane
1122TetCA	1,1,2,2-tetrachloroethane
112TCA	1,1,2-trichloroethane
11DCA	1,1-dichloroethane
11DCE	1,1-dichloroethene
124TMB	1,2,4-trimethylbenzene
12DCA	1,2-dichloroethane
12DCB	1,2-dichlorobenzene
135TMB	1,3,5-trimethylbenzene
13DCB	1,3-dichlorobenzene
14DCB	1,4-dichlorobenzene
2MeNAPH	2-methyl naphthalene
BENZ	benzene
BTEX	combined masses of benzene, toluene, ethylbenzene, and total xylenes (Gasoline Range Aromatics)
C11,C13&C15	combined masses of undecane, tridecane, and pentadecane (C11+C13+C15) (Diesel Range Alkanes)
c12DCE	cis-1,2-dichloroethene
CCl4	carbon tetrachloride
CHC13	chloroform
ClBENZ	chlorobenzene
ct12DCE	cis- & trans-1,2-dichloroethene
EtBENZ	ethylbenzene
mpXYL	m-, p-xylene
MTBE	methyl t-butyl ether
NAPH	naphthalene
OCT	octane
oXYL	o-xylene
PCE	tetrachloroethene
PENTADEC	pentadecane
PHEN	phenanthrene
t12DCE	trans-1,2-dichloroethene
TCE	trichloroethene
TMBs	combined masses of 1,3,5-trimethylbenzene and 1,2,4-trimethylbenzene
TOL	toluene
TPH	total petroleum hydrocarbons

SUMMARY OF SAMPLING RATE CALIBRATION FOR AGI UNIVERSAL SAMPLER IN AQUEOUS PHASES

INTRODUCTION:

The Amplified Geochemical Imaging, LLC (AGI) passive vapor sampler is designed to be used for soil gas, water, sediment pore water, and air sampling. This document describes the process used to calibrate the sampler's compound specific sampling or uptake rates in aqueous phases.

Sampling rates are measured following AGI's "Standard Practice for Determining the Sampling Rate of Passive Diffusion Samplers in Various Environmental Media": SPG-SOP-0493. Rates are used to calculate dissolved phase concentrations of volatile and semi-volatile contaminants in water. The calibration process is summarized in three parts: Part 1: shallow water, Part 2: deep water, and Part 3: sediment.

PURPOSE:

The purpose of this document is to:

1. Summarize the test protocol,
2. Summarize the methodology for analysis of data,
3. Present general results for generating concentration calibration of the AGI Universal Sampler

Principle of Operation of the AGI Samper

The AGI Universal Sampler is designed with solid adsorbents enclosed inside a tubular microporous PTFE membrane. When placed in water, the pores and hydrophobic nature of the PTFE keep liquid water from entering the membrane until a water head of about 34 feet is reached. The membrane will not keep water vapor from entering but the adsorbents are very hydrophobic and through testing validated to be unaffected by this moisture vapor. In shallow water, <34', volatile and semi-volatile compounds will partition from the dissolved water into the air phase in the PTFE membrane according to Henry's Law. This partitioning is instantaneous and within seconds-minutes, the compound is adsorbed by the adsorbent inside the sealed tube. Because the diffusivity in air is about 10,000 times higher than the diffusivity in water, the sampling rate is controlled by the water contact area of the membrane that allows the Henry's Law effect to occur. This contact area is set by the membrane diameter and length of the sealed tube, which is fixed in AGI's manufacturing process.

Henry's law as well as diffusivity, which are fundamentally incorporated into the sampling rate, are affected by temperature, T, and follow an Arrhenius equation H_T = Hr x exp([-Ea/R](1/Tr - 1/T)). Because a 5°C temperature change can make a 15% change in sampling rate, the temperature of the sampled water should be known to get the most precise concentration.

The membrane pore size is also small enough that colloidal particles and microbes cannot pass through the membrane. This keeps the adsorbent from getting contaminated and eliminates any need to add preservative or chilling during storage or transportation.

When the water pressure exceeds the water entry pressure of the membrane, about 34 feet of water, the water becomes in contact with the solid adsorbent. Under this condition the compounds in the water will partition from the water into the solid. The partitioning coefficient, K_{AW}, can be approximated by the octanol-water coefficient, K_{OW}, but has been measured more precisely in the lab for AGI's specific solid adsorbent. The sampling rate is the product of the sampling rate at <34' of water and the K_{AW}.

In sediment, the sampler measures pore-water concentration, which is generally agreed to be the preferred measurement as it is more indicative of bioavailability. In sediment the volumetric

availability of water to the sampler is reduced by the volume fraction solids in the sediment, which typically varies from zero to 35%, but can be has high at 73% in well packed and broad particle size distribution sediments. As a result, sampling rates in sediment are multiplied by the fraction pore water in the sediment to determine concentration.

PART 1: Calibration in shallow water

Part 1 summarizes the work in shallow water generating calibration data, evaluating the physical and chemical factors affecting the sampling rate, and measurement of the actual sampling rates or regression calibration equations needed to determine concentrations.

Sample Generation in water

In this calibration work, solutions of analytes at known concentrations were formulated in clean 4 liter smoked glass jugs by injecting microliter measured amounts of environmental standards using a calibrated syringe into pure or deionized water and stirring for a minimum of 2 hours but generally overnight. Headspace in the jugs was minimized and generally less than 1% by volume during the tests. Jugs were temperature controlled by placing them in a water filled cooler, chilled via a cooper tubing loop in the cooler. Temperature was measured with a certified digital temperature gauge and an average value used for each temperature experiment.

AGI samplers were weighted so they won't float and placed in the jugs at time zero. They were removed at various intervals to generate samples along with duplicates that showed mass increasing with exposure time. The sampler exposure time was selected to span minutes to hours and was generally reduced for high concentration tests to maintain uptake with time in roughly the linear dynamic range. Samplers were removed and dried with a paper towel and returned to their original container for analysis. They were analyzed by AGI's 8260C (SPG-WI-318 or SPG-WI-10028) method in duplicate, which is based on EPA SW846 Method 8260C.

Water samples were also taken and measured at an outside accredited lab using EPA SW846 Method 8260B. The concentrations agreed well with the calculated concentrations based on the standard certification, jug volume, and syringe injection. The variability of the outside lab 8260B values were found to be high, so for the sampling rate calculations we used the concentrations based on syringe dosing.

Calibrations were run at five concentrations, nominally at 6, 24, 118, 590, 1420 ug/L and five temperatures nominally at 5, 10, 15, 20, and 25 degrees centigrade. Samples were taken at 4 different exposure times. Samples were run in duplicate. A total of 176 data points were generated using 28 compounds from AGI's standard compounds list. Tridecane and pentadecane were not evaluated due to their very low solubility in water. In addition, another 23 compounds were tested using an 8260 liquid standard at nominal concentrations of 0.5, 1.0, 5.0, 15, 95, and 470 ug/L at a temperature typical of groundwater, 15°C. This is a living calibration and as additional data are generated, they may be qualified and added to this data set to improve the precision of the sampling rate calibration and broaden the compound list.

Key Variable Effects

As expected from theory, at short to moderate exposure times, mass will increase roughly linearly proportional to exposure time, as well as proportional to concentration, and exponentially with temperature following Arrhenius law. Temperature affects the Henry's law as well as diffusivity in water. Sampling rate is generally independent of concentration and time at mass values significantly below saturation. In the following sections we have characterized the sampling rate for each compound as affected by temperature and also developed calibrations using regression which account for the minor impact of time, and mass.

Concentration using Simple Sampling Rate Determination

A simple way to determine concentration is to measure mass on the AGI sampler, divide by exposure time, and divide by sampling rate, SR.

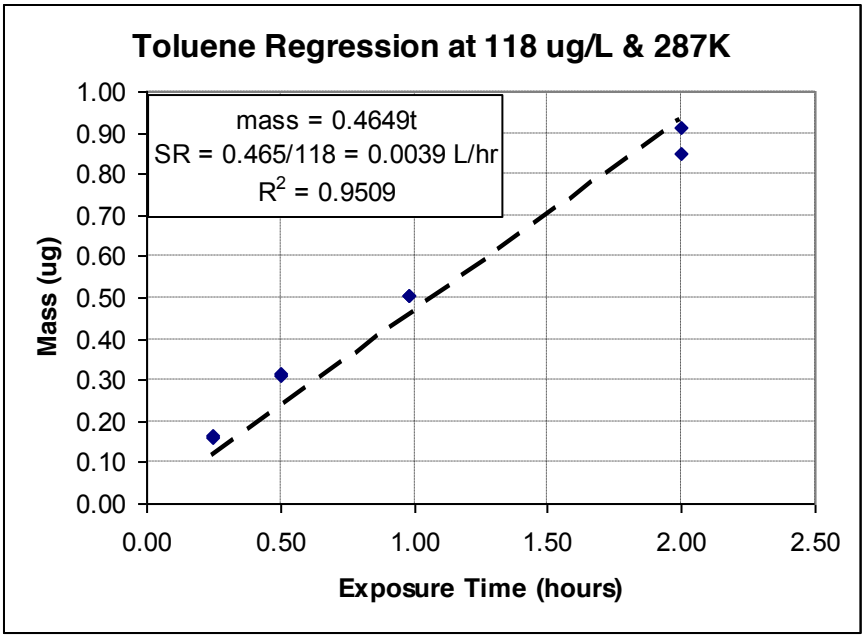
Conc [ug/L] = mass/time/SR (1)

The sampling rate can be determined via measurements of mass versus time at a known concentration and temperature according to the following modification of equation (1).

SR = mass/time/concentration (2)

Sampling rates in L/hr were determined by measuring the trend or regression mass uptake versus time and dividing by the concentration. A measurement like this will use 8 data points (4 times x 2 samples). Such a sampling rate can be measured at any concentration and temperature.

The chart to the right shows a plot of mass versus time for water at 118 ug/L and 287K (actual data from a single run). Slope of 0.465 ug/hr divided by the concentration of 118 ug/L yields a sampling rate, SR, of 0.0039 L/hr.



SR's typically range from about 0.004 to 0.007 L/hr at 15°C. Table A shows SR's measured for our standard compound list at 5 temperatures.

Rigorous Concentration using Regression

A preferred method for determining concentration that will yield improved accuracy over a wide range of concentrations, exposure times, and temperatures is to use all data in a regression analysis, which allows adjustments for the minor non-linear influences of mass and time as well as the effects of temperature. This step is done by regressing equation (1) or a universal version of equation (1):

$$Conc = (mass)^{b} / (time)^{-d} / [-SRo * \exp(-Ea/R/T)] \quad (3)$$

The subtle non-linear effects of mass and time will be evident in the deviation of coefficients b and d from 1.0. This regression generates four constants b, d, SRo, and –Ea/R by regressing ln(conc) versus ln(mass), ln(time), 1/temp. These four constants can be used to determine concentration via the equation:

$$Conc = (mass)^{b} / (time)^{-d} / [-SRo \times \exp(-Ea/R(1/T))] \quad (4)$$

Where conc is in ug/L, mass is in ug, time in hours, T in degrees Kelvin.

Equation (4) an be also expressed at a reference temperature, Tr, such as 15°C by

$$Conc = (mass)^{b} / (time)^{-d} / [-SRr \times \exp(-Ea/R(1/Tr-1/T))] \quad (5)$$

This step allows sampling rates, SRr, at any reference temperature, Tr, and for any analyte to easily be compared. The values of SRr at 293.14K can be found in Table A.

When sampling times are between 0 and 4 hours, using the 4 constant equation (5) is preferred. For concentrations from about 5 to 1500 ug/L one hour exposure times generally give the lowest error, typically with average error of 6-20% and with total error range of 12%-32%. For low concentrations where sampling times are greater than 4 hours, it is preferred to use equation (1) to avoid unrealistic effects from the coefficient d or to set d to 1.0. In such a case SR in equation (1) can be substituted with [SRr x exp(-Ea/R(1/Tr-1/T))] to use an SR representative of the well temperature, T.

The chart to the right is a plot of the calculated concentration from the 4 constant regression compared to the dosed concentration. Agreement is excellent for the 176 data points.

However, there does appear to be a slight high bias of 8.6% over the full range of this data, although it is well within acceptable limits of variability.

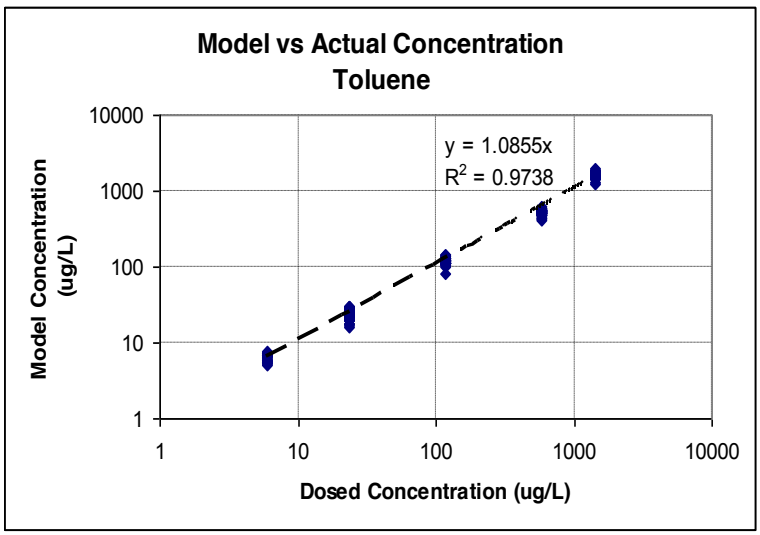


Table B shows the tabulated summary of the 4 constants regression with Rsq values and error estimates for the 4 constants for each analyte. Most regression Rsq values are 0.99 or greater for each analyte. In general, -Ea/R is about 2400+/-400, b is about 0.9, d is about -0.75, and SR(15°C) ranges from .004 L/hr to 0.007 L/hr increasing with MW of the compound.

Error Estimates

The error in the water concentration values will depend on both the error in mass from the analytical method as well as the error in the concentration calibration. Table C shows the error in the mass values from the 8260C low sensitivity method.

The standard error of the regression and standard errors of the constants can be found in table B. For each compound we have measured the error between the derived concentration and the actual concentration. The error tends to be lowest at our recommended exposure time of one hour as shown by the example for Toluene to the right.

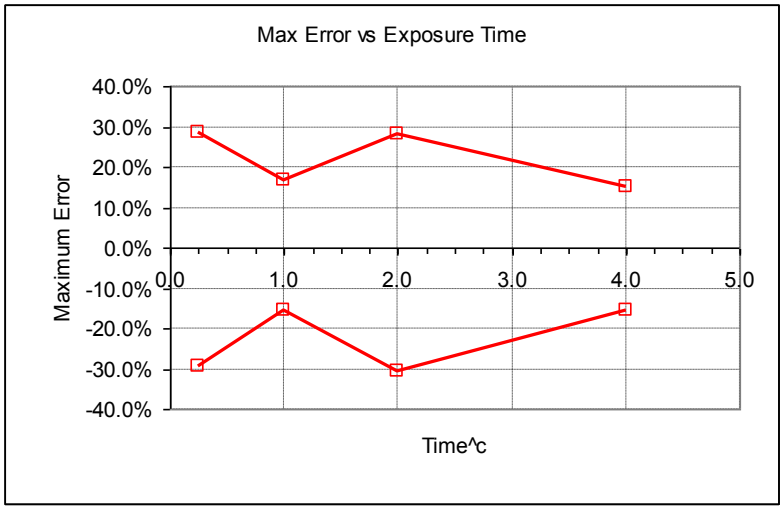

Table D shows the total average error in water concentration by compound as well as the low and high error. The average ranges from about 6% to 20%, which is similar to the analytical method errors. The low and high errors range from 12% to 32% and include contribution from measurement errors in both time and temperature.

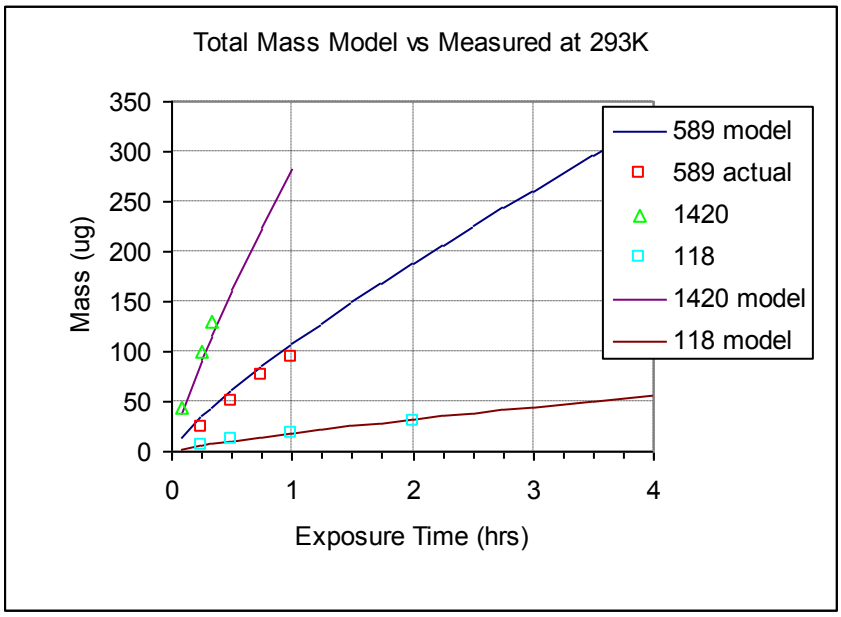
Sorbent Saturation

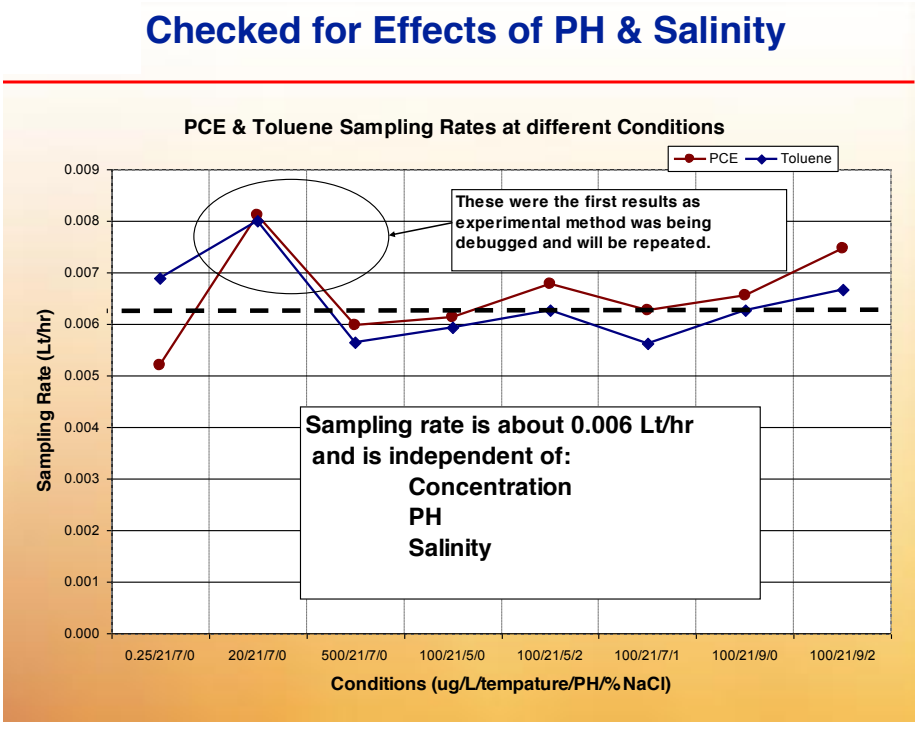
As mass increases on a solid sorbent and approaches saturation, reverse diffusion can occur causing the sampling rate to drop. Eventually the mass level will reach a maximum steady state value at any concentration. A rate of mass uptake with time that deviates significantly from linear, indicates that sorbent saturation could be an issue. When using equation (1), staying in the linear range to avoid the effects of adsorbent saturation is important. We recommend keeping the total mass on the sampler below 50 ug or flagging when this is exceeded.

The 4 constant regression accounts for some of the non linearity allowing good accuracy at higher mass levels. From the experimental data we have found this safe range can be extended to 100 ug or higher as shown in the chart below. This chart compares total mass of all compounds (excluding heavy alkanes, which have solubility issues) versus time in comparison to that predicted from the 4-constant concentration equation.



Effect of PH and Salinity

Because neither PH nor salinity is known to have a significant impact on Henry's law or diffusivity in water, we did not expect them to have a significant impact on sampling rate. To confirm this, experiments were run varying PH from 5 to 9 and NaCl content from 0 to 2%. The chart below shows no significant impact for combinations of PH and NaCl content over this range on the sampling rate of toluene in water at 21°C.

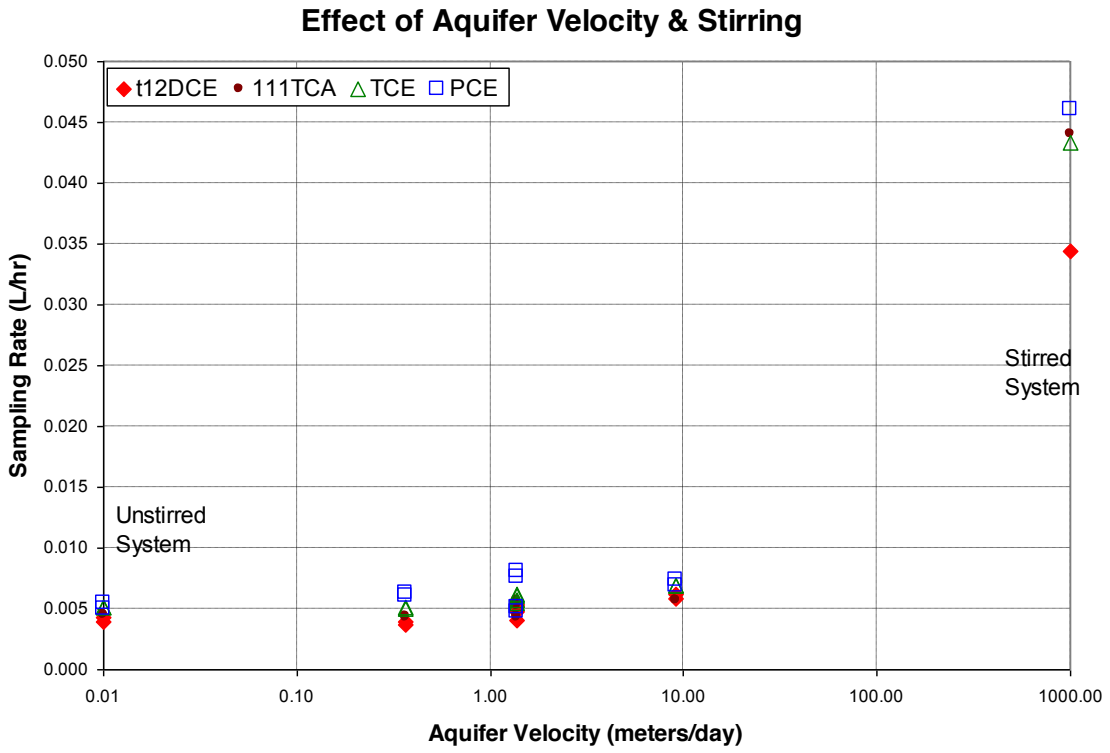


Impact of Aquifer Velocity

The velocity in most aquifers is quite slow, typically a meter/day or less. Occasionally water flow could be much higher such as encountered in karst aquifers, streams or rivers. Mass transfer coefficients are higher in high flow conditions, which will lead to higher sampling rates. We validated that a highly stirred system had sampling rates about 10 times higher than those that were non-stirred. We decided to evaluate the effect of aquifer velocity.

A test apparatus was built comprising a 3" PVC pipe tee filled with clean sand in each of the horizontal straight legs and screened to leave the center open. A test solution was run through this system using a variable flow pump and AGI samplers were placed into the simulated well through the vertical leg of the tee. Tests were run to examine the effect of velocity by varying the pumping rate and hence water velocity.

The chart below shows no significant effect of aquifer velocity up to a speed of about 10 meters/day. At velocities significantly above this, similar to a stirred system, sampling rates are about 10 times higher.

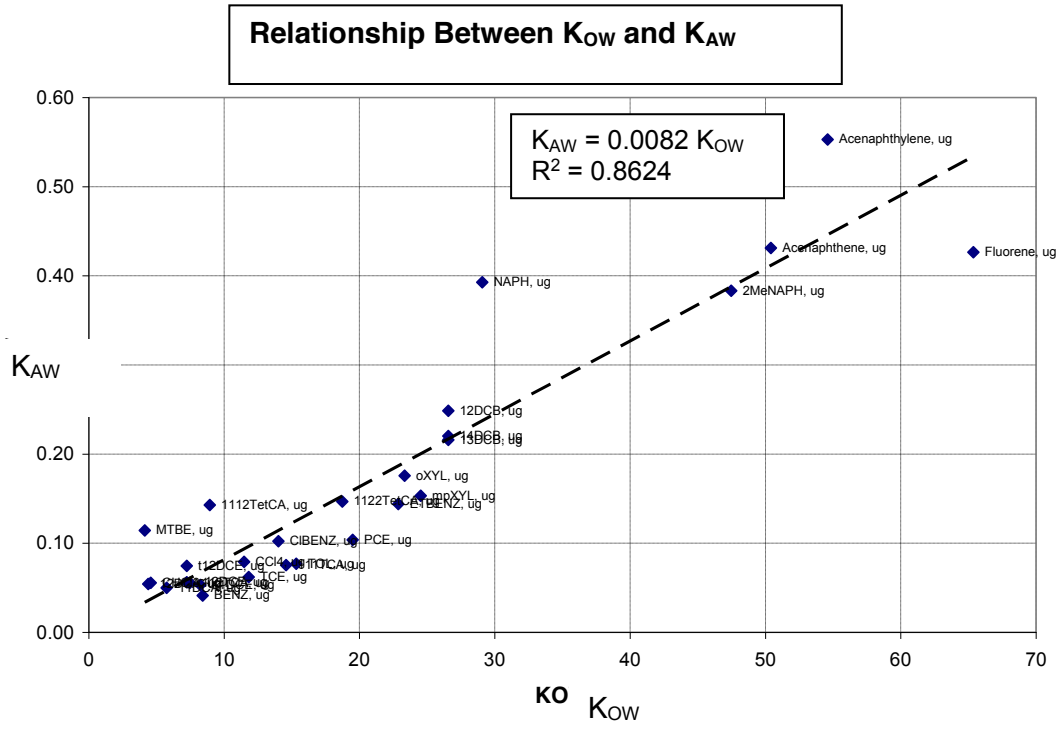


Part 2: Calibration in Deep (>34') water

Part 2 describes the effect of deep water on the AGI sampler and summarizes the effects on sampling rate and concentration measurement.

When the water pressure exceeds the water entry pressure of the membrane, about 34 feet of water, the water becomes in direct contact with the solid adsorbent. Under this condition the compounds in the water will partition from the water into the solid. The portioning coefficient is closely related to the octanol-water coefficient, K_{OW}, but has been measured more precisely in the lab for AGI's specific solid adsorbent, K_{AW}. The sampling rate for deep water is the product of the sampling rate at <34' of water and the K_{AW}.

Measurement of the K_{AW} was done in a one liter stainless steel vessel pressurized with nitrogen to simulate water heads above 34' of water. Pressures of up to 465 psig or 200' of water head were used. The sampling rate change was the same at all pressures above 34' of water. The K_{AW} was determined as the ratio between the mass or sampling rate above 34' of head to the rate at <34' of head and is shown in the chart below.



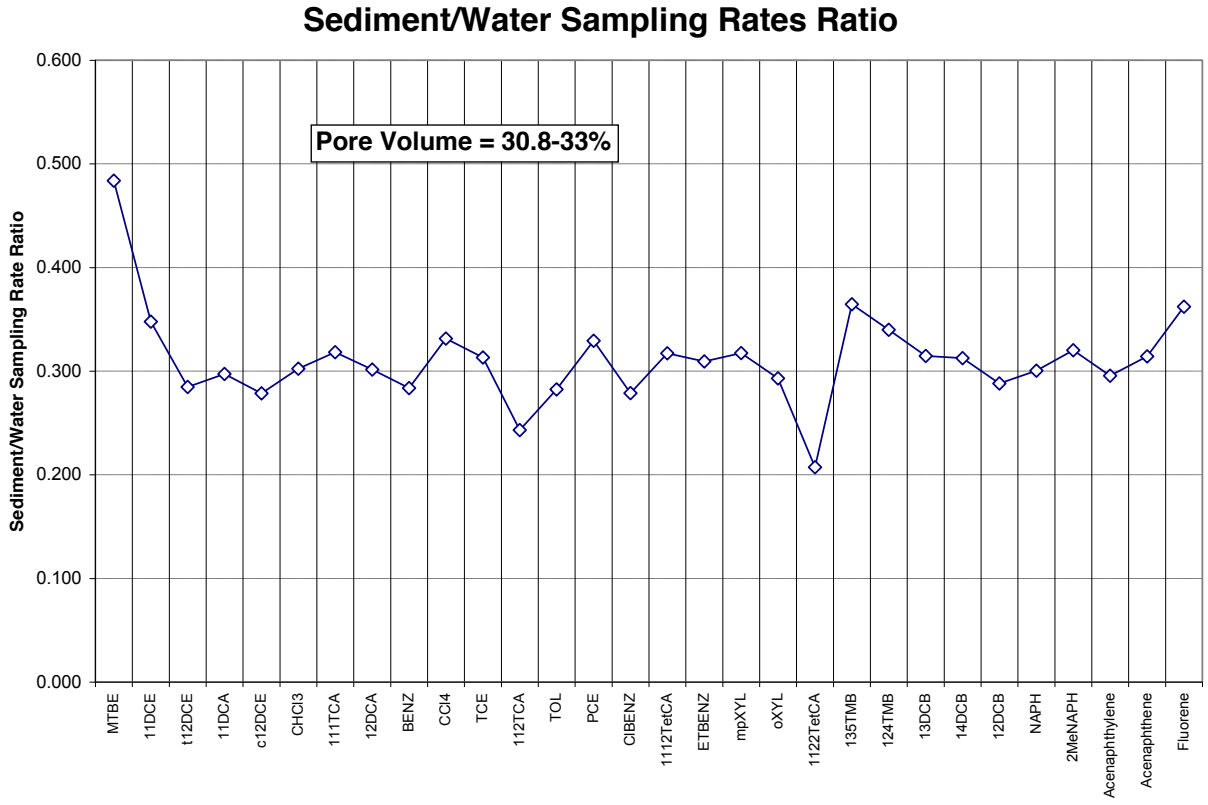
Part 3: Calibration in Sediment

Part 3 describes the effect of sediment solids or sediment pore volume on the sampling rate and concentration measurement.

In sediment, the sampler measures pore water concentration, which is generally agreed to be the preferred measurement as it is more indicative of bioavailability. In sediment the volumetric availability of water to the sampler is reduced by the volume fraction solids in the sediment. As a result sampling rates in sediment are multiplied by the fraction pore water to determine

concentration. Pore water fraction can range from 1.0 for water without sediment to as low as 0.25. Typically most sediments have pore fractions of 0.9 to 0.65.

A sampling rate study was done with water and with water added into a well-packed sorted sand. Pore water fraction in this test was measured between 30.8% and 33% by volume. Below is a plot of the ratio of sampling rates measured in the sediment to open water. The average ratio is equal to the pore water fraction confirming that sampling rate in sediment is on average equal to the product of pore water fraction times the sampling rate in water.



Summary

The AGI Sampler can be used to determine the concentration of volatile and semi-volatile compounds in a water phase. This requires knowing the exposure time and water temperature. It also requires knowing if the sample is above or below 34' of water head and if the water has a velocity above 10 meters/day. Regressions of large amounts of data were used to generate a four constant equation to generate concentration values in water. Potential error in the concentration values is excellent typically less than 25%.

AMPLIFIED GEOCHEMICAL IMAGING, LLC

Laboratory Report

Site: Comal & San Marcos Rivers August Sampling

Prepared for:

SWCA Environmental Consultants
10245 Little York Road
Suite 600
San Antonio, TX
UNITED STATES

Prepared on:
September 10, 2015
(Revised September 15, 2015)

Project Summary and Objective

Amplified Geochemical Imaging, LLC. (AGI) provided the AGI Environmental Survey used at:

Comal & San Marcos Rivers August Sampling

The service provided by AGI included delivery of the required quantity of AGI Universal Samplers, analysis by the method described below for the requested organic compounds, reporting of the data, and contour mapping (as needed).

This report includes results for only the samples noted under the Laboratory Sample Report section. If contour maps are part of the project deliverable, the maps will be prepared and issued under a separate report cover, upon receipt of a usable sitemap (electronic) and compound choices for contouring.

Quality Assurance Statement

The AGI Laboratory, at Amplified Geochemical Imaging's facility in Newark, DE USA, operates under the guidelines of its ISO Standard 17025 DoD ELAP accreditation, and its Quality Assurance Manual, Operating Procedures, and Methods (SPG-SOP-0462).

For this project, the analytical method, results, and observations reported do [ ] do not [√] fall within the scope of AGI's ISO 17025 accreditation.

Screening/Concentration Method

The AGI Universal Samplers are analyzed at AGI's fixed laboratory using thermal desorption-gas chromatography/mass spectrometry (TD-GC/MS) instrumentation following modified U.S. EPA Method 8260 (SPG-WI-0292) which includes the following:

- **BFB Tuning Frequency:** A BFB tune is analyzed at the start of each analytical run and after every 30 samples.
- **Initial Calibration:** A minimum of a five point calibration curve is analyzed prior to the analysis of samples.
- **Initial Calibration Verification (ICV):** Following the calibration a second-source reference standard is analyzed to verify the accuracy of the calibration. Acceptance criteria for the ICV is +/- 30%.
- **Linearity of Target Compounds:** If the RSD of any target analyte is less than or equal to 25% then average response factor can be used for quantitation. If the RSD exceeds 25% for a target compound a regression equation can be used for quantitation.
- **Continuing Calibration Verification:** After every 10 samples, and at the end of each analytical batch, a mid-level second-source Reference Standard is analyzed. The acceptance criteria for all target analytes in the reference standards are +/- 50% of the true value.
- **Method Blank:** Analyzed prior to the analysis of field samples and every 30 samples.

Note: Analyte levels reported for the field-deployed AGI Universal Samplers that exceed trip and method blank levels, and/or the reporting limit, are more likely to have originated from on-site sources.

Media Sampled:	WATER
Chemist - sample analysis:	Kelly J Stringham
Chemist - data processor:	Kelly J Stringham
Chemist - data review:	Ian McMullen

Method Deviations: None

Please note that data file names ending with R are rerun samples using the second pair of sorbers, in which the original results were not reported. Data file names ending in D are duplicate analysis results for the second set of sorbers from the same sampler, and are reported.

Additional Report Information

- Comments
- Laboratory Sample Report
- Chain of Custody
- Installation and Retrieval Log
- Analytical Results and Key
- Concentration Calculation Method Summary
- Total Ion Chromatograms

Project Specific Comments

Due to an instrument malfunction, samples were analyzed on two different instruments. The second instrument had an elevated TPH background, therefore the TPH values for samples analyzed on the second instrument were found to have artificially higher TPH values reported. Samples analyzed on the second instrument included: 767203, -204, -205, -210, and -221. Relative impact of the elevated TPH background can be seen in sample 767221, which was an unused sampler analyzed on the second instrument and was found to have 0.65ug of TPH.

This report was revised at the request of SWCA to report only the trip blank designated on the chain of custody, 00767214.

Survey period [1]	Samplers were installed on August 13, 2015 and retrieved on August 27, 2015 for an exposure time of 14 days.
Tamper seal intact:	Yes
Date received:	8/28/15 11:00 am By: Scott Kirlin
COC returned:	Yes

Comments:

None.

1 - Installation start to end of retrieval, as reported. See installation and retrieval log for individual deployment and retrieval dates and times (i.e., sampler exposure time).

General Comments

Analytical QA/QC

Laboratory instrumentation consists of gas chromatographs equipped with mass selective detectors, coupled with automated thermal desorption units. Sample preparation involves cutting the tip off the bottom of the AGI Universal Sampler, and transferring one or more "sorbers" to a thermal desorption tube for analysis. The insertion/retrieval cord prevents soil, water and other interferences from coming in contact with the adsorbent. No further sample preparation is required. Any replicate sorbers not consumed in the initial analysis will be discarded fifteen (15) days from the date of the laboratory report.

Data are archived and stored in a secure manner as per AGI's Quality Assurance program (SPG-SOP-0462).

Total petroleum hydrocarbons (TPH), gasoline-range petroleum hydrocarbons (GRPH), and/or diesel range petroleum hydrocarbons (DRPH), when reported, are calculated using the area under the peaks observed in m/z 55 and 57 selected ion chromatograms. Quantitation of the mass values was performed using the response factor for a specific alkane (present in the calibration standards). TPH values include the entire chromatogram and provide estimates for aliphatic hydrocarbon ranges of C4 to C20. GRPH and DRPH include only the relevant regions of the chromatograms and provide estimates for C4 to C10 and C10 to C20 aliphatic hydrocarbons, respectively.

Trip blanks were provided to document potential exposures that were not part of the signal of interest (e.g., impact during sampler shipment, installation and/or retrieval, and storage). The trip blanks are identically manufactured and packaged AGI Universal Samplers to those samplers deployed in the field . The trip blanks remain unopened during all phases of the project. Levels reported on the trip blanks may indicate potential impact to the samplers other than the contaminant source of interest.

Unresolved peak envelopes (UPEs) are represented as a series of compound peaks clustered together around a central gas chromatograph elution time in the total ion chromatogram. UPEs may be indicative of complex fluid mixtures. UPEs observed early in the chromatograms are considered to indicate presence of more volatile fluids, while UPEs observed later in the chromatogram may indicate the presence of less volatile fluids. Multiple UPEs may indicate the presence of multiple complex fluids.

Total ion chromatograms (TICs) are included in the Attachments. The eight-digit serial number of each sampler is incorporated in the TIC identification (e.g., 12345678.D represents AGI Universal Sampler 12345678).

General Comments

Soil Gas Sampling

For soil gas sampling, the AGI Environmental Survey reports mass levels migrating through the open pore spaces of the soil and diffusing through the sampler membrane for sorption by the engineered, hydrophobic adsorbents, housed within the membrane tube. During the migration of the soil gas away from the source to the AGI Universal Sampler, the vapors are subject to a variety of attenuation factors. The soil gas masses reported on the samplers compare favorably with the concentrations reported in the soil or groundwater (e.g., where soil gas levels are reported at greater levels to other sampled locations on the site, the matrix data should reveal the same pattern, and vice versa). However, due to a variety of factors, a perfect comparison between matrix data and soil gas levels can rarely be achieved.

Soil gas concentrations (µg/m3) are calculated following the method described in the Additional Report Information section.

Soil gas signals reported by this method cannot be correlated specifically to soil adsorbed, groundwater, and /or free-phase contamination. The soil gas signal reported from each AGI Universal Sampler can evolve from all of these sources. Differentiation between soil and groundwater contamination can only be achieved with prior knowledge of the site history (i.e., the site is known to have groundwater contamination only).

Air Sampling

For indoor, outdoor, and crawlspace air sampling, the AGI Environmental Survey reports mass levels present in the air and diffusing through the sampler membrane for sorption by the engineered adsorbents housed within the membrane tube.

Air concentrations (µg/m3) are calculated following the method described in the Additional Report Information section.

Groundwater and Sediment Porewater Sampling

For groundwater and sediment porewater sampling, the AGI Environmental Survey reports the mass levels of compounds present in the water which, when coming in contact with the sampler membrane, partitions out of solution, and diffuses through the sampler membrane for sorption by the engineered adsorbents.

Water concentrations (µg/L) are calculated using the quantified mass, exposure period and the compound specific uptake rate. The rates were measured under controlled experimental conditions. The uptake rates are corrected for water pressure (depth of the AGI Universal Sampler below the water table), water temperature and the aquifer flow rate. For sediment porewater, the uptake rate is corrected for the reduced volume of water in the sediment, by multiplying the uptake rate by the pore water fraction.

SUMMARY OF SAMPLING RATE CALIBRATION FOR AGI UNIVERSAL SAMPLER IN AQUEOUS PHASES

INTRODUCTION:

The Amplified Geochemical Imaging, LLC (AGI) passive vapor sampler is designed to be used for soil gas, water, sediment pore water, and air sampling. This document describes the process used to calibrate the sampler's compound specific sampling or uptake rates in aqueous phases.

Sampling rates are measured following AGI's "Standard Practice for Determining the Sampling Rate of Passive Diffusion Samplers in Various Environmental Media": SPG-SOP-0493. Rates are used to calculate dissolved phase concentrations of volatile and semi-volatile contaminants in water. The calibration process is summarized in three parts: Part 1: shallow water, Part 2: deep water, and Part 3: sediment.

PURPOSE:

The purpose of this document is to:

1. Summarize the test protocol,
2. Summarize the methodology for analysis of data,
3. Present general results for generating concentration calibration of the AGI Universal Sampler

Principle of Operation of the AGI Samper

The AGI Universal Sampler is designed with solid adsorbents enclosed inside a tubular microporous PTFE membrane. When placed in water, the pores and hydrophobic nature of the PTFE keep liquid water from entering the membrane until a water head of about 34 feet is reached. The membrane will not keep water vapor from entering but the adsorbents are very hydrophobic and through testing validated to be unaffected by this moisture vapor. In shallow water, <34', volatile and semi-volatile compounds will partition from the dissolved water into the air phase in the PTFE membrane according to Henry's Law. This partitioning is instantaneous and within seconds-minutes, the compound is adsorbed by the adsorbent inside the sealed tube. Because the diffusivity in air is about 10,000 times higher than the diffusivity in water, the sampling rate is controlled by the water contact area of the membrane that allows the Henry's Law effect to occur. This contact area is set by the membrane diameter and length of the sealed tube, which is fixed in AGI's manufacturing process.

Henry's law as well as diffusivity, which are fundamentally incorporated into the sampling rate, are affected by temperature, T, and follow an Arrhenius equation $H_T = Hr \times \exp([-Ea/R](1/Tr - 1/T))$. Because a 5°C temperature change can make a 15% change in sampling rate, the temperature of the sampled water should be known to get the most precise concentration.

The membrane pore size is also small enough that colloidal particles and microbes cannot pass through the membrane. This keeps the adsorbent from getting contaminated and eliminates any need to add preservative or chilling during storage or transportation.

When the water pressure exceeds the water entry pressure of the membrane, about 34 feet of water, the water becomes in contact with the solid adsorbent. Under this condition the compounds in the water will partition from the water into the solid. The partitioning coefficient, K_{AW}, can be approximated by the octanol-water coefficient, K_{OW}, but has been measured more precisely in the lab for AGI's specific solid adsorbent. The sampling rate is the product of the sampling rate at <34' of water and the K_{AW}.

In sediment, the sampler measures pore-water concentration, which is generally agreed to be the preferred measurement as it is more indicative of bioavailability. In sediment the volumetric

availability of water to the sampler is reduced by the volume fraction solids in the sediment, which typically varies from zero to 35%, but can be has high at 73% in well packed and broad particle size distribution sediments. As a result, sampling rates in sediment are multiplied by the fraction pore water in the sediment to determine concentration.

PART 1: Calibration in shallow water

Part 1 summarizes the work in shallow water generating calibration data, evaluating the physical and chemical factors affecting the sampling rate, and measurement of the actual sampling rates or regression calibration equations needed to determine concentrations.

Sample Generation in water

In this calibration work, solutions of analytes at known concentrations were formulated in clean 4 liter smoked glass jugs by injecting microliter measured amounts of environmental standards using a calibrated syringe into pure or deionized water and stirring for a minimum of 2 hours but generally overnight. Headspace in the jugs was minimized and generally less than 1% by volume during the tests. Jugs were temperature controlled by placing them in a water filled cooler, chilled via a cooper tubing loop in the cooler. Temperature was measured with a certified digital temperature gauge and an average value used for each temperature experiment.

AGI samplers were weighted so they won't float and placed in the jugs at time zero. They were removed at various intervals to generate samples along with duplicates that showed mass increasing with exposure time. The sampler exposure time was selected to span minutes to hours and was generally reduced for high concentration tests to maintain uptake with time in roughly the linear dynamic range. Samplers were removed and dried with a paper towel and returned to their original container for analysis. They were analyzed by AGI's 8260C (SPG-WI-318 or SPG-WI-10028) method in duplicate, which is based on EPA SW846 Method 8260C.

Water samples were also taken and measured at an outside accredited lab using EPA SW846 Method 8260B. The concentrations agreed well with the calculated concentrations based on the standard certification, jug volume, and syringe injection. The variability of the outside lab 8260B values were found to be high, so for the sampling rate calculations we used the concentrations based on syringe dosing.

Calibrations were run at five concentrations, nominally at 6, 24, 118, 590, 1420 ug/L and five temperatures nominally at 5, 10, 15, 20, and 25 degrees centigrade. Samples were taken at 4 different exposure times. Samples were run in duplicate. A total of 176 data points were generated using 28 compounds from AGI's standard compounds list. Tridecane and pentadecane were not evaluated due to their very low solubility in water. In addition, another 23 compounds were tested using an 8260 liquid standard at nominal concentrations of 0.5, 1.0, 5.0, 15, 95, and 470 ug/L at a temperature typical of groundwater, 15°C. This is a living calibration and as additional data are generated, they may be qualified and added to this data set to improve the precision of the sampling rate calibration and broaden the compound list.

Key Variable Effects

As expected from theory, at short to moderate exposure times, mass will increase roughly linearly proportional to exposure time, as well as proportional to concentration, and exponentially with temperature following Arrhenius law. Temperature affects the Henry's law as well as diffusivity in water. Sampling rate is generally independent of concentration and time at mass values significantly below saturation. In the following sections we have characterized the sampling rate for each compound as affected by temperature and also developed calibrations using regression which account for the minor impact of time, and mass.

Concentration using Simple Sampling Rate Determination

A simple way to determine concentration is to measure mass on the AGI sampler, divide by exposure time, and divide by sampling rate, SR.

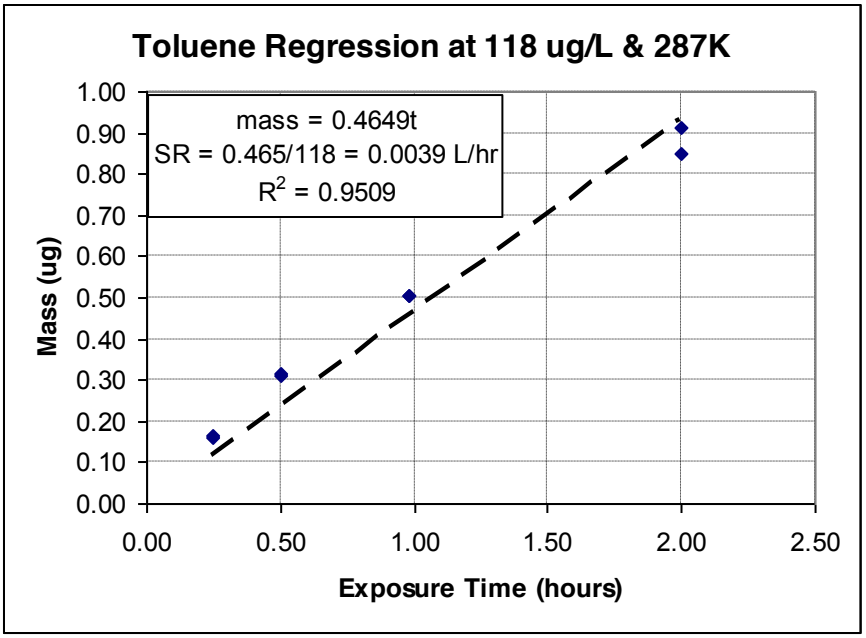
Conc [ug/L] = mass/time/SR (1)

The sampling rate can be determined via measurements of mass versus time at a known concentration and temperature according to the following modification of equation (1).

SR = mass/time/concentration (2)

Sampling rates in L/hr were determined by measuring the trend or regression mass uptake versus time and dividing by the concentration. A measurement like this will use 8 data points (4 times x 2 samples). Such a sampling rate can be measured at any concentration and temperature.

The chart to the right shows a plot of mass versus time for water at 118 ug/L and 287K (actual data from a single run). Slope of 0.465 ug/hr divided by the concentration of 118 ug/L yields a sampling rate, SR, of 0.0039 L/hr.



SR's typically range from about 0.004 to 0.007 L/hr at 15°C. Table A shows SR's measured for our standard compound list at 5 temperatures.

Rigorous Concentration using Regression

A preferred method for determining concentration that will yield improved accuracy over a wide range of concentrations, exposure times, and temperatures is to use all data in a regression analysis, which allows adjustments for the minor non-linear influences of mass and time as well as the effects of temperature. This step is done by regressing equation (1) or a universal version of equation (1):

$$Conc = (mass)^{b} / (time)^{-d} / [-SRo * \exp(-Ea/R/T)] \quad (3)$$

The subtle non-linear effects of mass and time will be evident in the deviation of coefficients b and d from 1.0. This regression generates four constants b, d, SRo, and –Ea/R by regressing ln(conc) versus ln(mass), ln(time), 1/temp. These four constants can be used to determine concentration via the equation:

$$Conc = (mass)^{b} / (time)^{-d} / [-SRo \times \exp(-Ea/R(1/T))] \quad (4)$$

Where conc is in ug/L, mass is in ug, time in hours, T in degrees Kelvin.

Equation (4) an be also expressed at a reference temperature, Tr, such as 15°C by

$$Conc = (mass)^{b} / (time)^{-d} / [-SRr \times \exp(-Ea/R(1/Tr-1/T))] \quad (5)$$

This step allows sampling rates, SRr, at any reference temperature, Tr, and for any analyte to easily be compared. The values of SRr at 293.14K can be found in Table A.

When sampling times are between 0 and 4 hours, using the 4 constant equation (5) is preferred. For concentrations from about 5 to 1500 ug/L one hour exposure times generally give the lowest error, typically with average error of 6-20% and with total error range of 12%-32%. For low concentrations where sampling times are greater than 4 hours, it is preferred to use equation (1) to avoid unrealistic effects from the coefficient d or to set d to 1.0. In such a case SR in equation (1) can be substituted with [SRr x exp(-Ea/R(1/Tr-1/T))] to use an SR representative of the well temperature, T.

The chart to the right is a plot of the calculated concentration from the 4 constant regression compared to the dosed concentration. Agreement is excellent for the 176 data points.

However, there does appear to be a slight high bias of 8.6% over the full range of this data, although it is well within acceptable limits of variability.

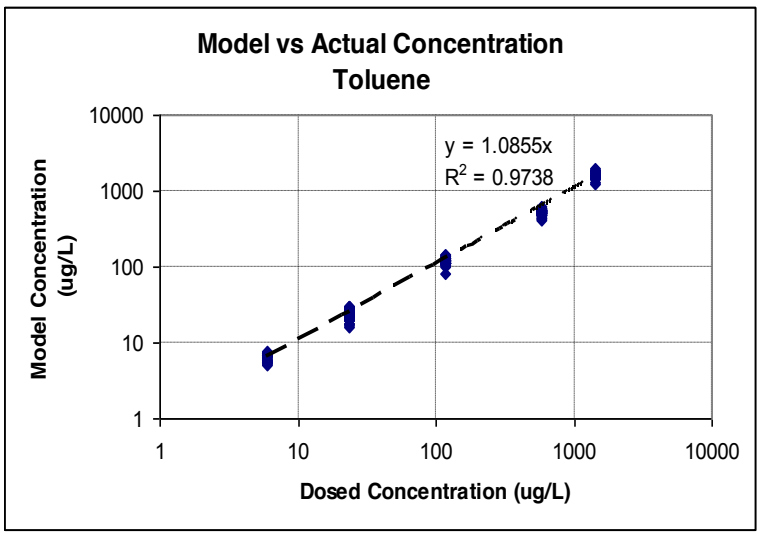


Table B shows the tabulated summary of the 4 constants regression with Rsq values and error estimates for the 4 constants for each analyte. Most regression Rsq values are 0.99 or greater for each analyte. In general, -Ea/R is about 2400+/-400, b is about 0.9, d is about -0.75, and SR(15°C) ranges from .004 L/hr to 0.007 L/hr increasing with MW of the compound.

Error Estimates

The error in the water concentration values will depend on both the error in mass from the analytical method as well as the error in the concentration calibration. Table C shows the error in the mass values from the 8260C low sensitivity method.

The standard error of the regression and standard errors of the constants can be found in table B. For each compound we have measured the error between the derived concentration and the actual concentration. The error tends to be lowest at our recommended exposure time of one hour as shown by the example for Toluene to the right.

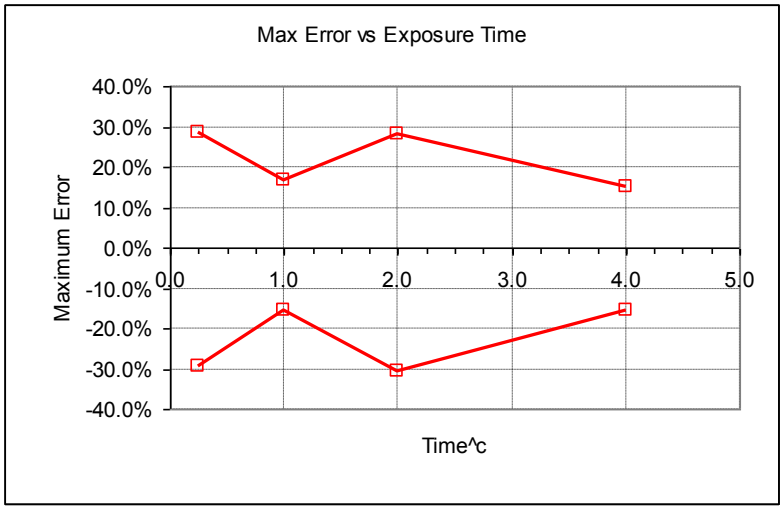

Table D shows the total average error in water concentration by compound as well as the low and high error. The average ranges from about 6% to 20%, which is similar to the analytical method errors. The low and high errors range from 12% to 32% and include contribution from measurement errors in both time and temperature.

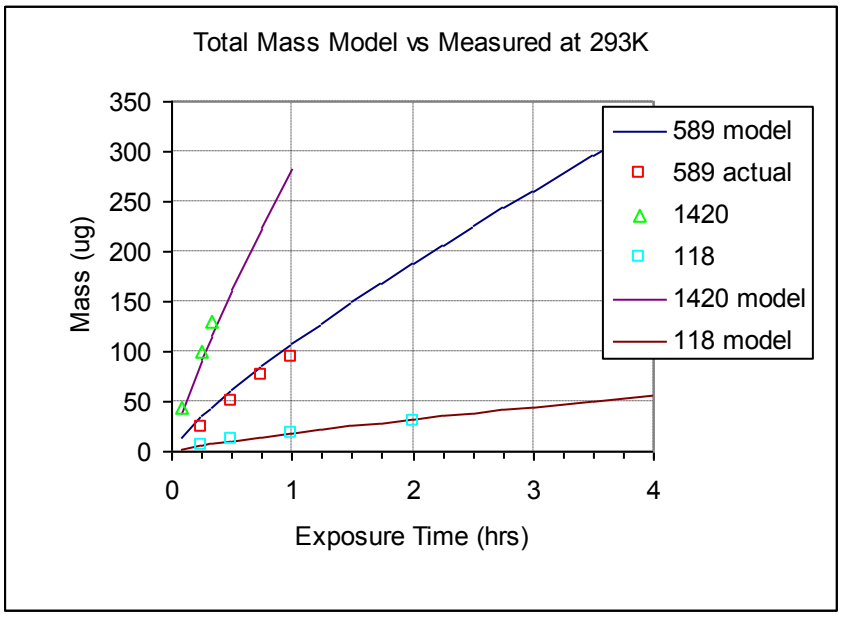
Sorbent Saturation

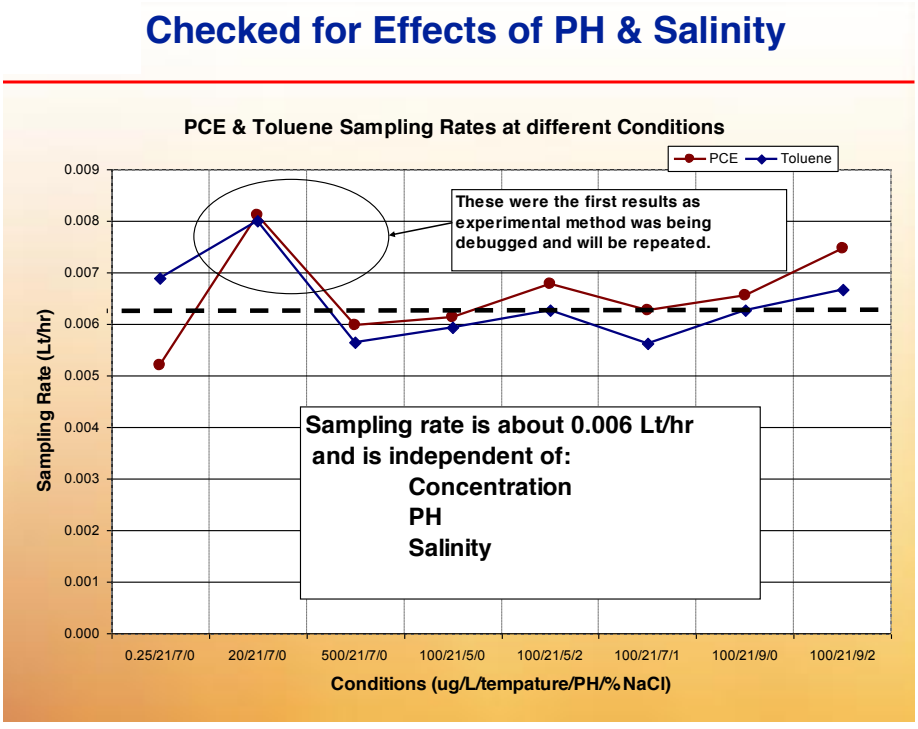
As mass increases on a solid sorbent and approaches saturation, reverse diffusion can occur causing the sampling rate to drop. Eventually the mass level will reach a maximum steady state value at any concentration. A rate of mass uptake with time that deviates significantly from linear, indicates that sorbent saturation could be an issue. When using equation (1), staying in the linear range to avoid the effects of adsorbent saturation is important. We recommend keeping the total mass on the sampler below 50 ug or flagging when this is exceeded.

The 4 constant regression accounts for some of the non linearity allowing good accuracy at higher mass levels. From the experimental data we have found this safe range can be extended to 100 ug or higher as shown in the chart below. This chart compares total mass of all compounds (excluding heavy alkanes, which have solubility issues) versus time in comparison to that predicted from the 4-constant concentration equation.



Effect of PH and Salinity

Because neither PH nor salinity is known to have a significant impact on Henry's law or diffusivity in water, we did not expect them to have a significant impact on sampling rate. To confirm this, experiments were run varying PH from 5 to 9 and NaCl content from 0 to 2%. The chart below shows no significant impact for combinations of PH and NaCl content over this range on the sampling rate of toluene in water at 21°C.

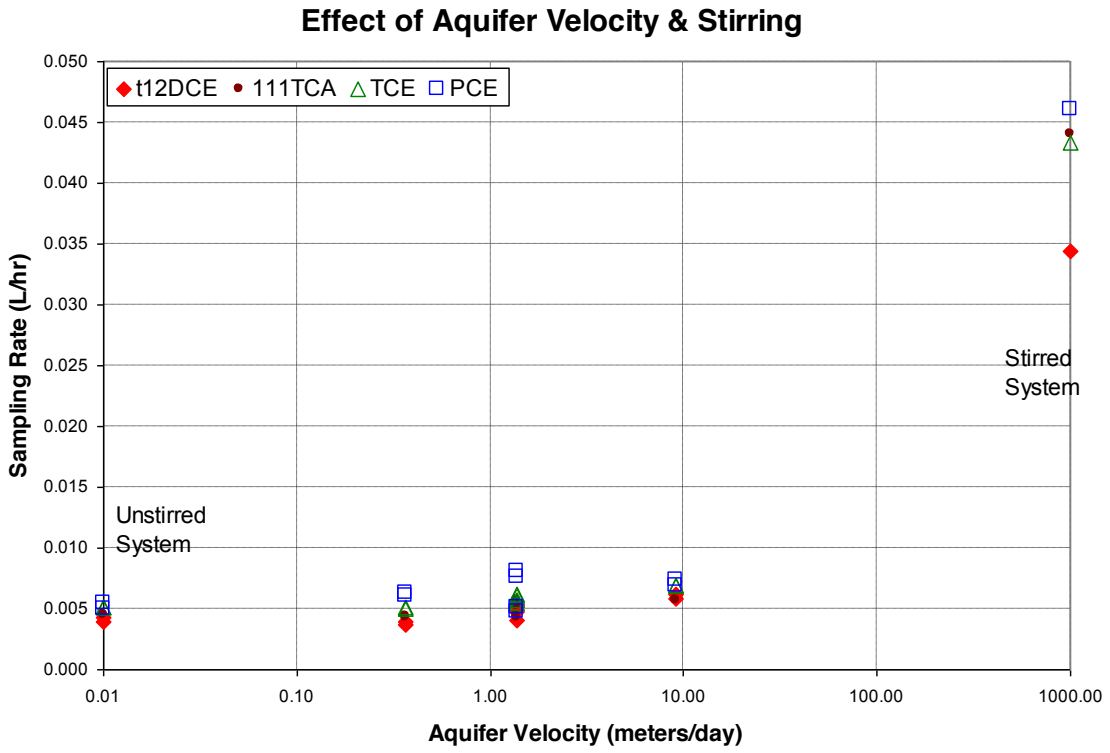


Impact of Aquifer Velocity

The velocity in most aquifers is quite slow, typically a meter/day or less. Occasionally water flow could be much higher such as encountered in karst aquifers, streams or rivers. Mass transfer coefficients are higher in high flow conditions, which will lead to higher sampling rates. We validated that a highly stirred system had sampling rates about 10 times higher than those that were non-stirred. We decided to evaluate the effect of aquifer velocity.

A test apparatus was built comprising a 3" PVC pipe tee filled with clean sand in each of the horizontal straight legs and screened to leave the center open. A test solution was run through this system using a variable flow pump and AGI samplers were placed into the simulated well through the vertical leg of the tee. Tests were run to examine the effect of velocity by varying the pumping rate and hence water velocity.

The chart below shows no significant effect of aquifer velocity up to a speed of about 10 meters/day. At velocities significantly above this, similar to a stirred system, sampling rates are about 10 times higher.

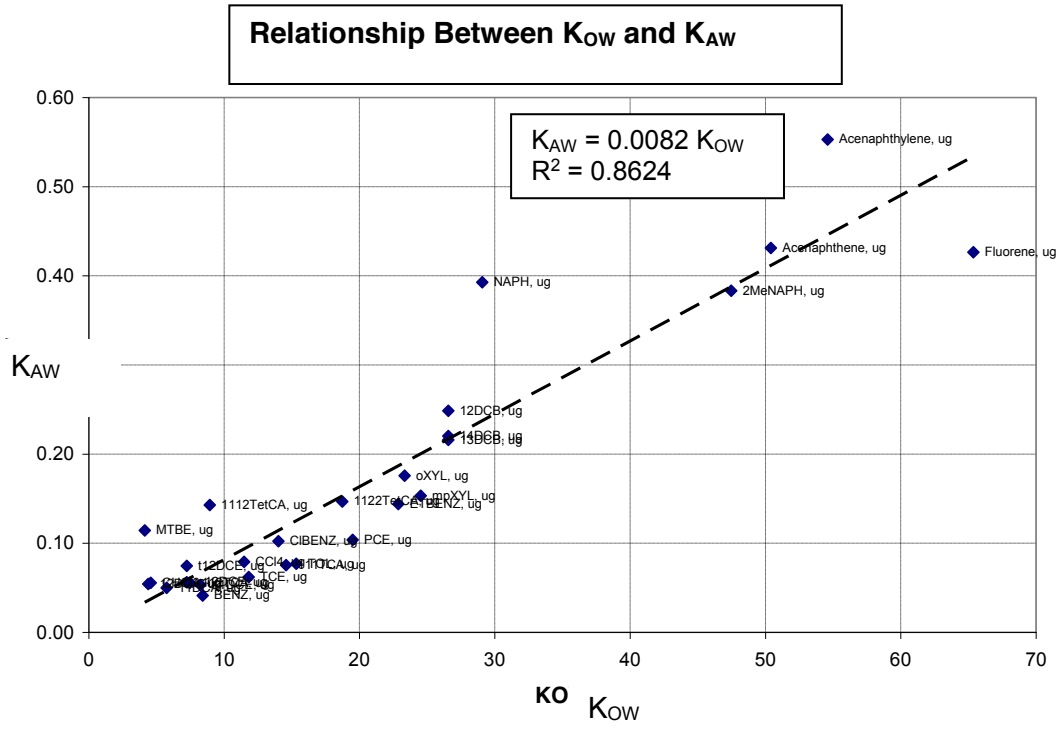


Part 2: Calibration in Deep (>34') water

Part 2 describes the effect of deep water on the AGI sampler and summarizes the effects on sampling rate and concentration measurement.

When the water pressure exceeds the water entry pressure of the membrane, about 34 feet of water, the water becomes in direct contact with the solid adsorbent. Under this condition the compounds in the water will partition from the water into the solid. The portioning coefficient is closely related to the octanol-water coefficient, K_{OW}, but has been measured more precisely in the lab for AGI's specific solid adsorbent, K_{AW}. The sampling rate for deep water is the product of the sampling rate at <34' of water and the K_{AW}.

Measurement of the K_{AW} was done in a one liter stainless steel vessel pressurized with nitrogen to simulate water heads above 34' of water. Pressures of up to 465 psig or 200' of water head were used. The sampling rate change was the same at all pressures above 34' of water. The K_{AW} was determined as the ratio between the mass or sampling rate above 34' of head to the rate at <34' of head and is shown in the chart below.



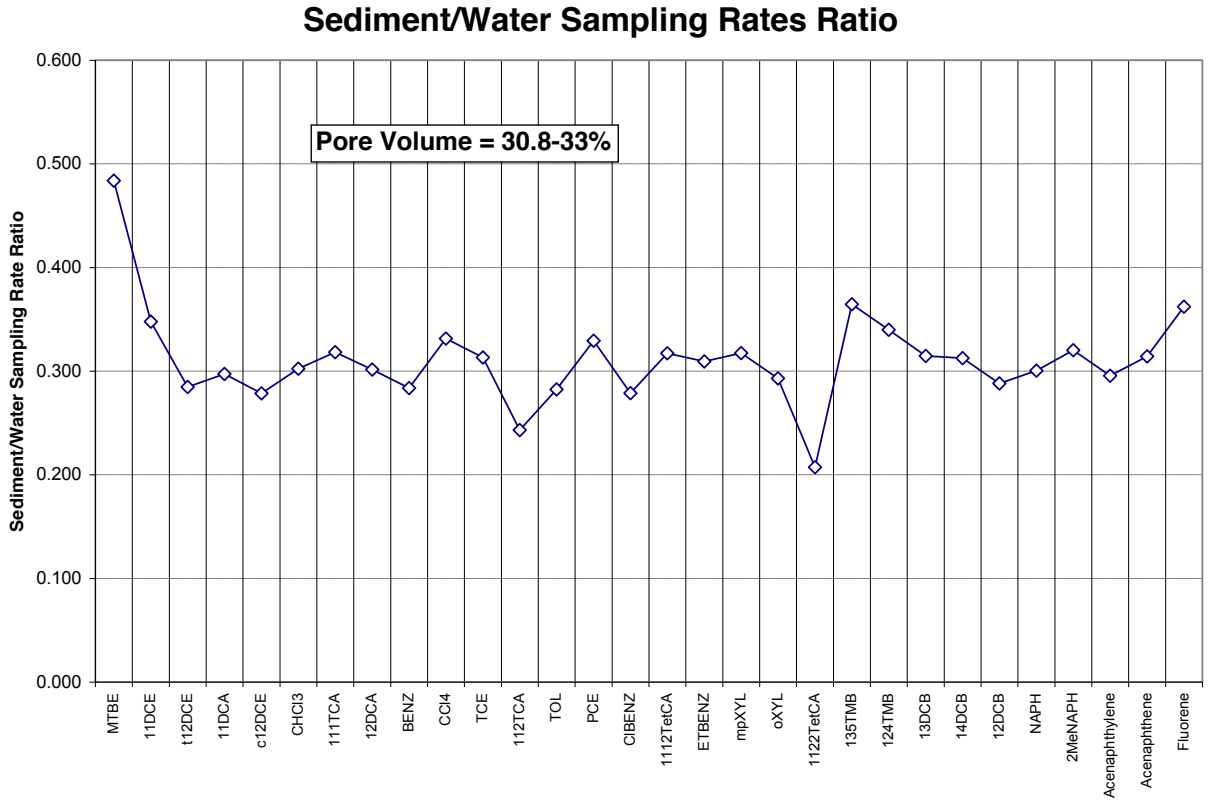
Part 3: Calibration in Sediment

Part 3 describes the effect of sediment solids or sediment pore volume on the sampling rate and concentration measurement.

In sediment, the sampler measures pore water concentration, which is generally agreed to be the preferred measurement as it is more indicative of bioavailability. In sediment the volumetric availability of water to the sampler is reduced by the volume fraction solids in the sediment. As a result sampling rates in sediment are multiplied by the fraction pore water to determine

concentration. Pore water fraction can range from 1.0 for water without sediment to as low as 0.25. Typically most sediments have pore fractions of 0.9 to 0.65.

A sampling rate study was done with water and with water added into a well-packed sorted sand. Pore water fraction in this test was measured between 30.8% and 33% by volume. Below is a plot of the ratio of sampling rates measured in the sediment to open water. The average ratio is equal to the pore water fraction confirming that sampling rate in sediment is on average equal to the product of pore water fraction times the sampling rate in water.



Summary

The AGI Sampler can be used to determine the concentration of volatile and semi-volatile compounds in a water phase. This requires knowing the exposure time and water temperature. It also requires knowing if the sample is above or below 34' of water head and if the water has a velocity above 10 meters/day. Regressions of large amounts of data were used to generate a four constant equation to generate concentration values in water. Potential error in the concentration values is excellent typically less than 25%.

Laboratory Report

Site: Comal & San Marcos Rivers
October Sampling

Prepared for:

SWCA Environmental Consultants
10245 Little York Road
Suite 600
San Antonio, TX
UNITED STATES

Prepared on:
October 30, 2015

Project Summary and Objective

Amplified Geochemical Imaging, LLC. (AGI) provided the AGI Environmental Survey used at:

Comal & San Marcos Rivers

October Sampling

The service provided by AGI included delivery of the required quantity of AGI Universal Samplers, analysis by the method described below for the requested organic compounds, reporting of the data, and contour mapping (as needed).

This report includes results for only the samples noted under the Laboratory Sample Report section. If contour maps are part of the project deliverable, the maps will be prepared and issued under a separate report cover, upon receipt of a usable sitemap (electronic) and compound choices for contouring.

Quality Assurance Statement

The AGI Laboratory, at Amplified Geochemical Imaging's facility in Newark, DE USA, operates under the guidelines of its ISO Standard 17025 DoD ELAP accreditation, and its Quality Assurance Manual, Operating Procedures, and Methods (SPG-SOP-0462).

For this project, the analytical method, results, and observations reported do [ ] do not [√] fall within the scope of AGI's ISO 17025 accreditation.

Screening/Concentration Method

The AGI Universal Samplers are analyzed at AGI's fixed laboratory using thermal desorption-gas chromatography/mass spectrometry (TD-GC/MS) instrumentation following modified U.S. EPA Method 8260 (SPG-WI-0292) which includes the following:

- **BFB Tuning Frequency:** A BFB tune is analyzed at the start of each analytical run and after every 30 samples.
- **Initial Calibration:** A minimum of a five point calibration curve is analyzed prior to the analysis of samples.
- **Initial Calibration Verification (ICV):** Following the calibration a second-source reference standard is analyzed to verify the accuracy of the calibration. Acceptance criteria for the ICV is +/- 30%.
- **Linearity of Target Compounds:** If the RSD of any target analyte is less than or equal to 25% then average response factor can be used for quantitation. If the RSD exceeds 25% for a target compound a regression equation can be used for quantitation.
- **Continuing Calibration Verification:** After every 10 samples, and at the end of each analytical batch, a mid-level second-source Reference Standard is analyzed. The acceptance criteria for all target analytes in the reference standards are +/- 50% of the true value.
- **Method Blank:** Analyzed prior to the analysis of field samples and every 30 samples.

Note: Analyte levels reported for the field-deployed AGI Universal Samplers that exceed trip and method blank levels, and/or the reporting limit, are more likely to have originated from on-site sources.

General Comments

Analytical QA/QC

Laboratory instrumentation consists of gas chromatographs equipped with mass selective detectors, coupled with automated thermal desorption units. Sample preparation involves cutting the tip off the bottom of the AGI Universal Sampler, and transferring one or more "sorbers" to a thermal desorption tube for analysis. The insertion/retrieval cord prevents soil, water and other interferences from coming in contact with the adsorbent. No further sample preparation is required. Any replicate sorbers not consumed in the initial analysis will be discarded fifteen (15) days from the date of the laboratory report.

Data are archived and stored in a secure manner as per AGI's Quality Assurance program (SPG-SOP-0462).

Total petroleum hydrocarbons (TPH), gasoline-range petroleum hydrocarbons (GRPH), and/or diesel range petroleum hydrocarbons (DRPH), when reported, are calculated using the area under the peaks observed in m/z 55 and 57 selected ion chromatograms. Quantitation of the mass values was performed using the response factor for a specific alkane (present in the calibration standards). TPH values include the entire chromatogram and provide estimates for aliphatic hydrocarbon ranges of C4 to C20. GRPH and DRPH include only the relevant regions of the chromatograms and provide estimates for C4 to C10 and C10 to C20 aliphatic hydrocarbons, respectively.

Trip blanks were provided to document potential exposures that were not part of the signal of interest (e.g., impact during sampler shipment, installation and/or retrieval, and storage). The trip blanks are identically manufactured and packaged AGI Universal Samplers to those samplers deployed in the field . The trip blanks remain unopened during all phases of the project. Levels reported on the trip blanks may indicate potential impact to the samplers other than the contaminant source of interest.

Unresolved peak envelopes (UPEs) are represented as a series of compound peaks clustered together around a central gas chromatograph elution time in the total ion chromatogram. UPEs may be indicative of complex fluid mixtures. UPEs observed early in the chromatograms are considered to indicate presence of more volatile fluids, while UPEs observed later in the chromatogram may indicate the presence of less volatile fluids. Multiple UPEs may indicate the presence of multiple complex fluids.

Total ion chromatograms (TICs) are included in the Attachments. The eight-digit serial number of each sampler is incorporated in the TIC identification (e.g., 12345678.D represents AGI Universal Sampler 12345678).

General Comments

Soil Gas Sampling

For soil gas sampling, the AGI Environmental Survey reports mass levels migrating through the open pore spaces of the soil and diffusing through the sampler membrane for sorption by the engineered, hydrophobic adsorbents, housed within the membrane tube. During the migration of the soil gas away from the source to the AGI Universal Sampler, the vapors are subject to a variety of attenuation factors. The soil gas masses reported on the samplers compare favorably with the concentrations reported in the soil or groundwater (e.g., where soil gas levels are reported at greater levels to other sampled locations on the site, the matrix data should reveal the same pattern, and vice versa). However, due to a variety of factors, a perfect comparison between matrix data and soil gas levels can rarely be achieved.

Soil gas concentrations (µg/m3) are calculated following the method described in the Additional Report Information section.

Soil gas signals reported by this method cannot be correlated specifically to soil adsorbed, groundwater, and /or free-phase contamination. The soil gas signal reported from each AGI Universal Sampler can evolve from all of these sources. Differentiation between soil and groundwater contamination can only be achieved with prior knowledge of the site history (i.e., the site is known to have groundwater contamination only).

Air Sampling

For indoor, outdoor, and crawlspace air sampling, the AGI Environmental Survey reports mass levels present in the air and diffusing through the sampler membrane for sorption by the engineered adsorbents housed within the membrane tube.

Air concentrations (µg/m3) are calculated following the method described in the Additional Report Information section.

Groundwater and Sediment Porewater Sampling

For groundwater and sediment porewater sampling, the AGI Environmental Survey reports the mass levels of compounds present in the water which, when coming in contact with the sampler membrane, partitions out of solution, and diffuses through the sampler membrane for sorption by the engineered adsorbents.

Water concentrations (µg/L) are calculated using the quantified mass, exposure period and the compound specific uptake rate. The rates were measured under controlled experimental conditions. The uptake rates are corrected for water pressure (depth of the AGI Universal Sampler below the water table), water temperature and the aquifer flow rate. For sediment porewater, the uptake rate is corrected for the reduced volume of water in the sediment, by multiplying the uptake rate by the pore water fraction.

SUMMARY OF SAMPLING RATE CALIBRATION FOR AGI UNIVERSAL SAMPLER IN AQUEOUS PHASES

INTRODUCTION:

The Amplified Geochemical Imaging, LLC (AGI) passive vapor sampler is designed to be used for soil gas, water, sediment pore water, and air sampling. This document describes the process used to calibrate the sampler's compound specific sampling or uptake rates in aqueous phases.

Sampling rates are measured following AGI's "Standard Practice for Determining the Sampling Rate of Passive Diffusion Samplers in Various Environmental Media": SPG-SOP-0493. Rates are used to calculate dissolved phase concentrations of volatile and semi-volatile contaminants in water. The calibration process is summarized in three parts: Part 1: shallow water, Part 2: deep water, and Part 3: sediment.

PURPOSE:

The purpose of this document is to:

1. Summarize the test protocol,
2. Summarize the methodology for analysis of data,
3. Present general results for generating concentration calibration of the AGI Universal Sampler

Principle of Operation of the AGI Samper

The AGI Universal Sampler is designed with solid adsorbents enclosed inside a tubular microporous PTFE membrane. When placed in water, the pores and hydrophobic nature of the PTFE keep liquid water from entering the membrane until a water head of about 34 feet is reached. The membrane will not keep water vapor from entering but the adsorbents are very hydrophobic and through testing validated to be unaffected by this moisture vapor. In shallow water, <34', volatile and semi-volatile compounds will partition from the dissolved water into the air phase in the PTFE membrane according to Henry's Law. This partitioning is instantaneous and within seconds-minutes, the compound is adsorbed by the adsorbent inside the sealed tube. Because the diffusivity in air is about 10,000 times higher than the diffusivity in water, the sampling rate is controlled by the water contact area of the membrane that allows the Henry's Law effect to occur. This contact area is set by the membrane diameter and length of the sealed tube, which is fixed in AGI's manufacturing process.

Henry's law as well as diffusivity, which are fundamentally incorporated into the sampling rate, are affected by temperature, T, and follow an Arrhenius equation H_T = Hr x exp([-Ea/R](1/Tr - 1/T)). Because a 5°C temperature change can make a 15% change in sampling rate, the temperature of the sampled water should be known to get the most precise concentration.

The membrane pore size is also small enough that colloidal particles and microbes cannot pass through the membrane. This keeps the adsorbent from getting contaminated and eliminates any need to add preservative or chilling during storage or transportation.

When the water pressure exceeds the water entry pressure of the membrane, about 34 feet of water, the water becomes in contact with the solid adsorbent. Under this condition the compounds in the water will partition from the water into the solid. The partitioning coefficient, K_{AW}, can be approximated by the octanol-water coefficient, K_{OW}, but has been measured more precisely in the lab for AGI's specific solid adsorbent. The sampling rate is the product of the sampling rate at <34' of water and the K_{AW}.

In sediment, the sampler measures pore-water concentration, which is generally agreed to be the preferred measurement as it is more indicative of bioavailability. In sediment the volumetric

availability of water to the sampler is reduced by the volume fraction solids in the sediment, which typically varies from zero to 35%, but can be has high at 73% in well packed and broad particle size distribution sediments. As a result, sampling rates in sediment are multiplied by the fraction pore water in the sediment to determine concentration.

PART 1: Calibration in shallow water

Part 1 summarizes the work in shallow water generating calibration data, evaluating the physical and chemical factors affecting the sampling rate, and measurement of the actual sampling rates or regression calibration equations needed to determine concentrations.

Sample Generation in water

In this calibration work, solutions of analytes at known concentrations were formulated in clean 4 liter smoked glass jugs by injecting microliter measured amounts of environmental standards using a calibrated syringe into pure or deionized water and stirring for a minimum of 2 hours but generally overnight. Headspace in the jugs was minimized and generally less than 1% by volume during the tests. Jugs were temperature controlled by placing them in a water filled cooler, chilled via a cooper tubing loop in the cooler. Temperature was measured with a certified digital temperature gauge and an average value used for each temperature experiment.

AGI samplers were weighted so they won't float and placed in the jugs at time zero. They were removed at various intervals to generate samples along with duplicates that showed mass increasing with exposure time. The sampler exposure time was selected to span minutes to hours and was generally reduced for high concentration tests to maintain uptake with time in roughly the linear dynamic range. Samplers were removed and dried with a paper towel and returned to their original container for analysis. They were analyzed by AGI's 8260C (SPG-WI-318 or SPG-WI-10028) method in duplicate, which is based on EPA SW846 Method 8260C.

Water samples were also taken and measured at an outside accredited lab using EPA SW846 Method 8260B. The concentrations agreed well with the calculated concentrations based on the standard certification, jug volume, and syringe injection. The variability of the outside lab 8260B values were found to be high, so for the sampling rate calculations we used the concentrations based on syringe dosing.

Calibrations were run at five concentrations, nominally at 6, 24, 118, 590, 1420 ug/L and five temperatures nominally at 5, 10, 15, 20, and 25 degrees centigrade. Samples were taken at 4 different exposure times. Samples were run in duplicate. A total of 176 data points were generated using 28 compounds from AGI's standard compounds list. Tridecane and pentadecane were not evaluated due to their very low solubility in water. In addition, another 23 compounds were tested using an 8260 liquid standard at nominal concentrations of 0.5, 1.0, 5.0, 15, 95, and 470 ug/L at a temperature typical of groundwater, 15°C. This is a living calibration and as additional data are generated, they may be qualified and added to this data set to improve the precision of the sampling rate calibration and broaden the compound list.

Key Variable Effects

As expected from theory, at short to moderate exposure times, mass will increase roughly linearly proportional to exposure time, as well as proportional to concentration, and exponentially with temperature following Arrhenius law. Temperature affects the Henry's law as well as diffusivity in water. Sampling rate is generally independent of concentration and time at mass values significantly below saturation. In the following sections we have characterized the sampling rate for each compound as affected by temperature and also developed calibrations using regression which account for the minor impact of time, and mass.

Concentration using Simple Sampling Rate Determination

A simple way to determine concentration is to measure mass on the AGI sampler, divide by exposure time, and divide by sampling rate, SR.

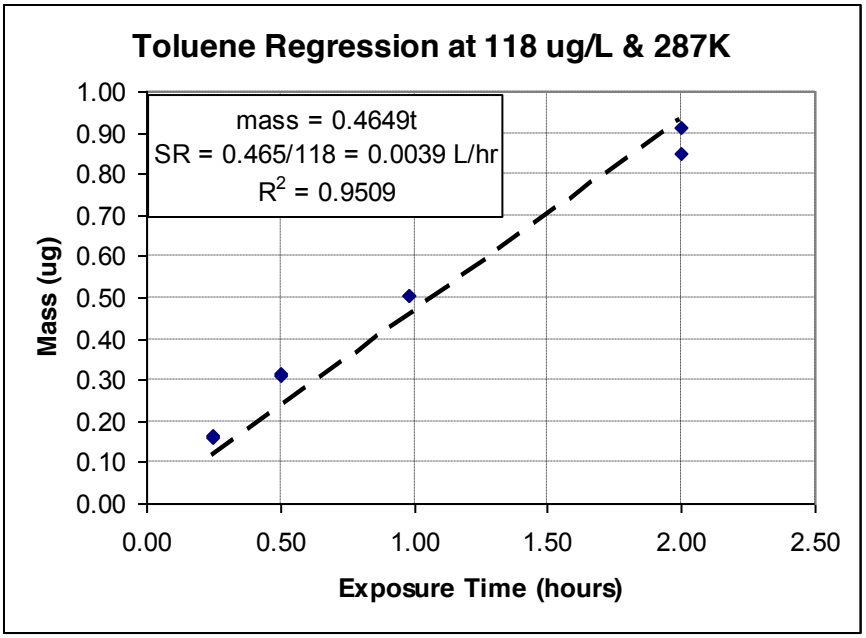
Conc [ug/L] = mass/time/SR (1)

The sampling rate can be determined via measurements of mass versus time at a known concentration and temperature according to the following modification of equation (1).

SR = mass/time/concentration (2)

Sampling rates in L/hr were determined by measuring the trend or regression mass uptake versus time and dividing by the concentration. A measurement like this will use 8 data points (4 times x 2 samples). Such a sampling rate can be measured at any concentration and temperature.

The chart to the right shows a plot of mass versus time for water at 118 ug/L and 287K (actual data from a single run). Slope of 0.465 ug/hr divided by the concentration of 118 ug/L yields a sampling rate, SR, of 0.0039 L/hr.



SR's typically range from about 0.004 to 0.007 L/hr at 15°C. Table A shows SR's measured for our standard compound list at 5 temperatures.

Rigorous Concentration using Regression

A preferred method for determining concentration that will yield improved accuracy over a wide range of concentrations, exposure times, and temperatures is to use all data in a regression analysis, which allows adjustments for the minor non-linear influences of mass and time as well as the effects of temperature. This step is done by regressing equation (1) or a universal version of equation (1):

$$Conc = (mass)^{b} / (time)^{-d} / [-SRo * \exp(-Ea/R/T)] \quad (3)$$

The subtle non-linear effects of mass and time will be evident in the deviation of coefficients b and d from 1.0. This regression generates four constants b, d, SRo, and –Ea/R by regressing ln(conc) versus ln(mass), ln(time), 1/temp. These four constants can be used to determine concentration via the equation:

$$Conc = (mass)^{b} / (time)^{-d} / [-SRo \times \exp(-Ea/R(1/T))] \quad (4)$$

Where conc is in ug/L, mass is in ug, time in hours, T in degrees Kelvin.

Equation (4) an be also expressed at a reference temperature, Tr, such as 15°C by

$$Conc = (mass)^{b} / (time)^{-d} / [-SRr \times \exp(-Ea/R(1/Tr-1/T))] \quad (5)$$

This step allows sampling rates, SRr, at any reference temperature, Tr, and for any analyte to easily be compared. The values of SRr at 293.14K can be found in Table A.

When sampling times are between 0 and 4 hours, using the 4 constant equation (5) is preferred. For concentrations from about 5 to 1500 ug/L one hour exposure times generally give the lowest error, typically with average error of 6-20% and with total error range of 12%-32%. For low concentrations where sampling times are greater than 4 hours, it is preferred to use equation (1) to avoid unrealistic effects from the coefficient d or to set d to 1.0. In such a case SR in equation (1) can be substituted with [SRr x exp(-Ea/R(1/Tr-1/T))] to use an SR representative of the well temperature, T.

The chart to the right is a plot of the calculated concentration from the 4 constant regression compared to the dosed concentration. Agreement is excellent for the 176 data points.

However, there does appear to be a slight high bias of 8.6% over the full range of this data, although it is well within acceptable limits of variability.

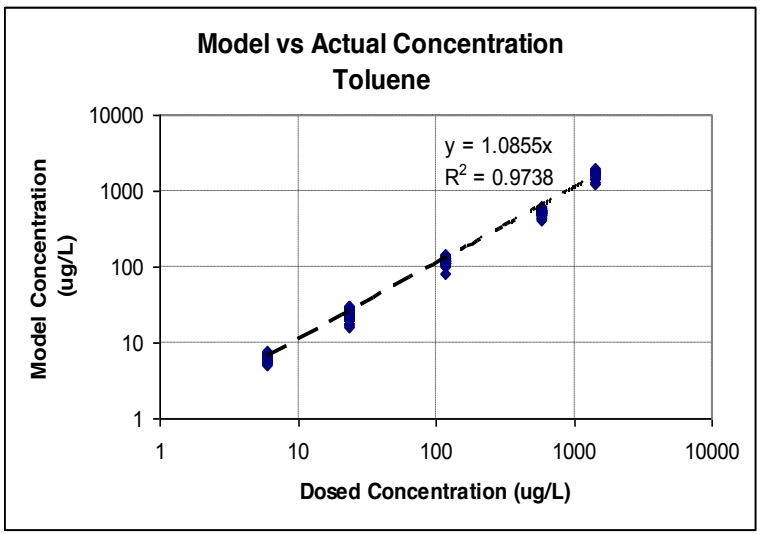


Table B shows the tabulated summary of the 4 constants regression with Rsq values and error estimates for the 4 constants for each analyte. Most regression Rsq values are 0.99 or greater for each analyte. In general, -Ea/R is about 2400+/-400, b is about 0.9, d is about -0.75, and SR(15°C) ranges from .004 L/hr to 0.007 L/hr increasing with MW of the compound.

Error Estimates

The error in the water concentration values will depend on both the error in mass from the analytical method as well as the error in the concentration calibration. Table C shows the error in the mass values from the 8260C low sensitivity method.

The standard error of the regression and standard errors of the constants can be found in table B. For each compound we have measured the error between the derived concentration and the actual concentration. The error tends to be lowest at our recommended exposure time of one hour as shown by the example for Toluene to the right.

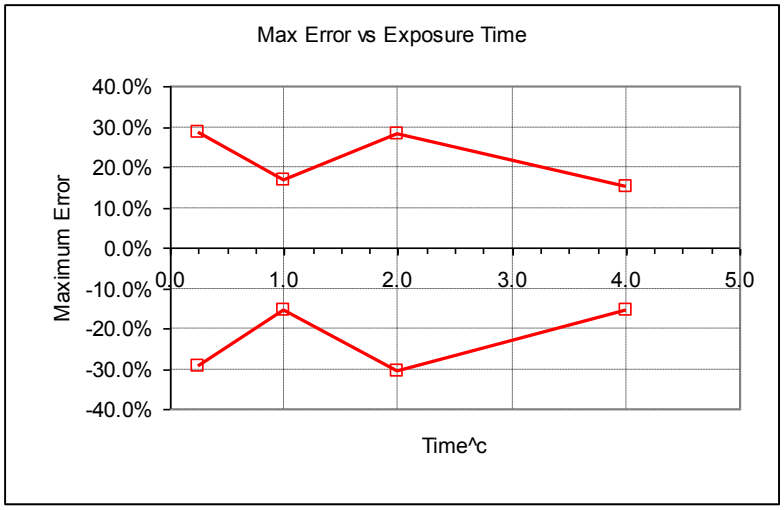

Table D shows the total average error in water concentration by compound as well as the low and high error. The average ranges from about 6% to 20%, which is similar to the analytical method errors. The low and high errors range from 12% to 32% and include contribution from measurement errors in both time and temperature.

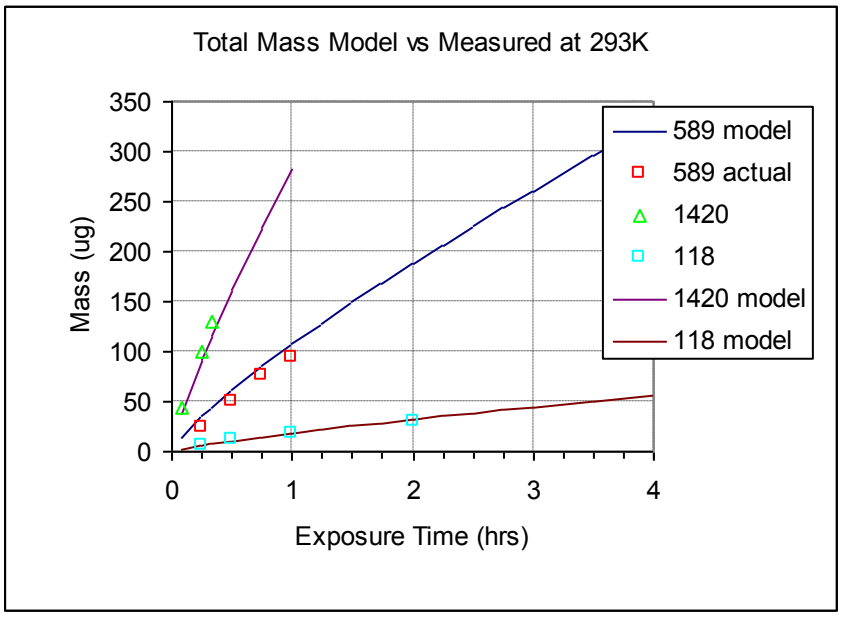
Sorbent Saturation

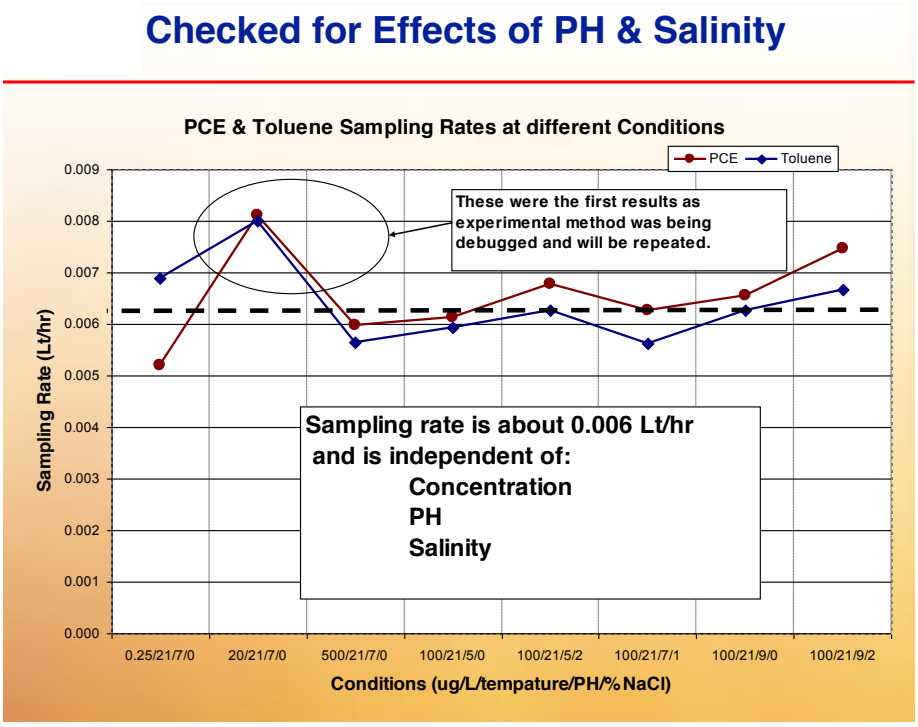
As mass increases on a solid sorbent and approaches saturation, reverse diffusion can occur causing the sampling rate to drop. Eventually the mass level will reach a maximum steady state value at any concentration. A rate of mass uptake with time that deviates significantly from linear, indicates that sorbent saturation could be an issue. When using equation (1), staying in the linear range to avoid the effects of adsorbent saturation is important. We recommend keeping the total mass on the sampler below 50 ug or flagging when this is exceeded.

The 4 constant regression accounts for some of the non linearity allowing good accuracy at higher mass levels. From the experimental data we have found this safe range can be extended to 100 ug or higher as shown in the chart below. This chart compares total mass of all compounds (excluding heavy alkanes, which have solubility issues) versus time in comparison to that predicted from the 4-constant concentration equation.



Effect of PH and Salinity

Because neither PH nor salinity is known to have a significant impact on Henry's law or diffusivity in water, we did not expect them to have a significant impact on sampling rate. To confirm this, experiments were run varying PH from 5 to 9 and NaCl content from 0 to 2%. The chart below shows no significant impact for combinations of PH and NaCl content over this range on the sampling rate of toluene in water at 21°C.

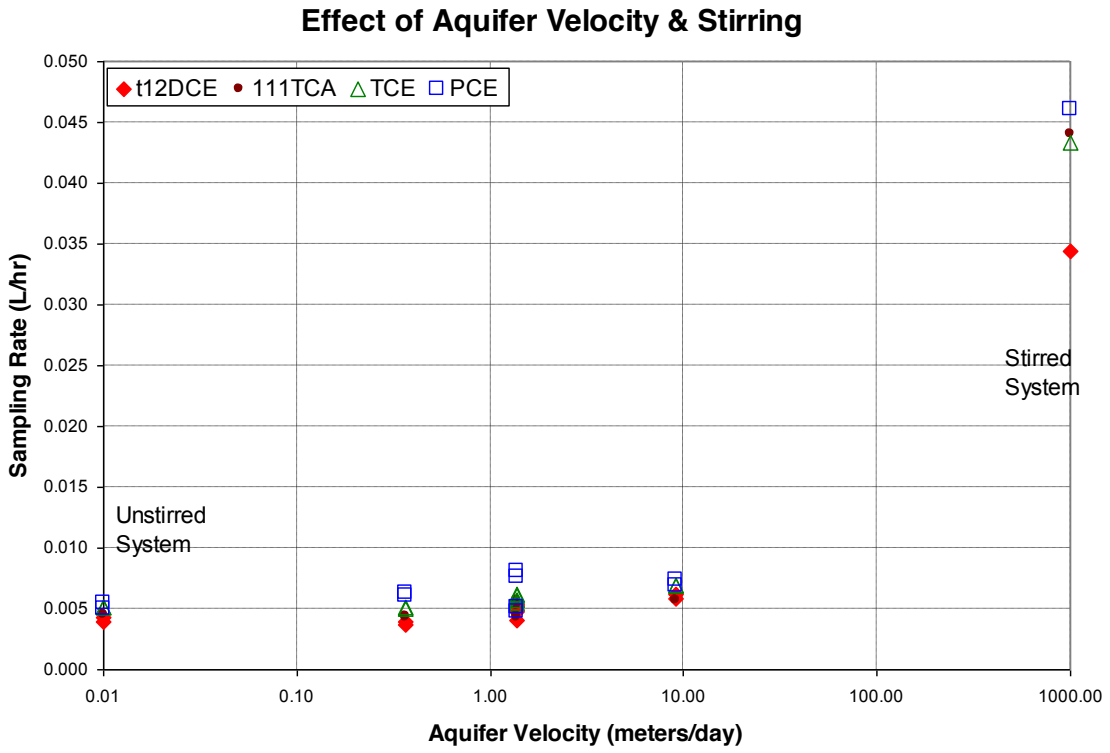


Impact of Aquifer Velocity

The velocity in most aquifers is quite slow, typically a meter/day or less. Occasionally water flow could be much higher such as encountered in karst aquifers, streams or rivers. Mass transfer coefficients are higher in high flow conditions, which will lead to higher sampling rates. We validated that a highly stirred system had sampling rates about 10 times higher than those that were non-stirred. We decided to evaluate the effect of aquifer velocity.

A test apparatus was built comprising a 3" PVC pipe tee filled with clean sand in each of the horizontal straight legs and screened to leave the center open. A test solution was run through this system using a variable flow pump and AGI samplers were placed into the simulated well through the vertical leg of the tee. Tests were run to examine the effect of velocity by varying the pumping rate and hence water velocity.

The chart below shows no significant effect of aquifer velocity up to a speed of about 10 meters/day. At velocities significantly above this, similar to a stirred system, sampling rates are about 10 times higher.

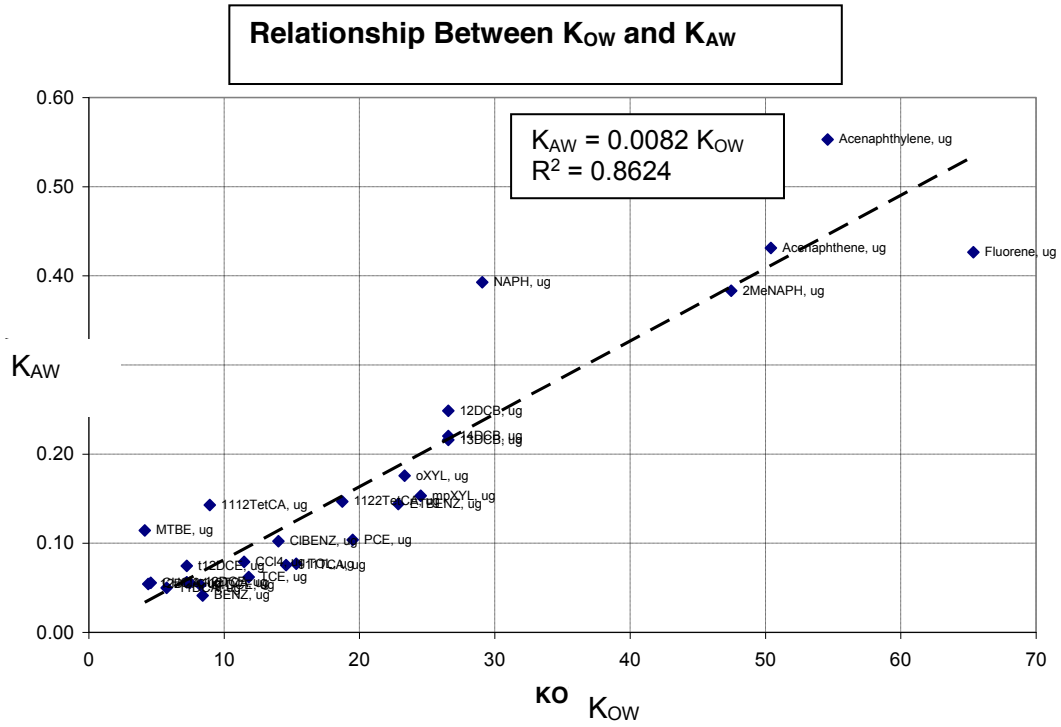


Part 2: Calibration in Deep (>34') water

Part 2 describes the effect of deep water on the AGI sampler and summarizes the effects on sampling rate and concentration measurement.

When the water pressure exceeds the water entry pressure of the membrane, about 34 feet of water, the water becomes in direct contact with the solid adsorbent. Under this condition the compounds in the water will partition from the water into the solid. The portioning coefficient is closely related to the octanol-water coefficient, K_{OW}, but has been measured more precisely in the lab for AGI's specific solid adsorbent, K_{AW}. The sampling rate for deep water is the product of the sampling rate at <34' of water and the K_{AW}.

Measurement of the K_{AW} was done in a one liter stainless steel vessel pressurized with nitrogen to simulate water heads above 34' of water. Pressures of up to 465 psig or 200' of water head were used. The sampling rate change was the same at all pressures above 34' of water. The K_{AW} was determined as the ratio between the mass or sampling rate above 34' of head to the rate at <34' of head and is shown in the chart below.



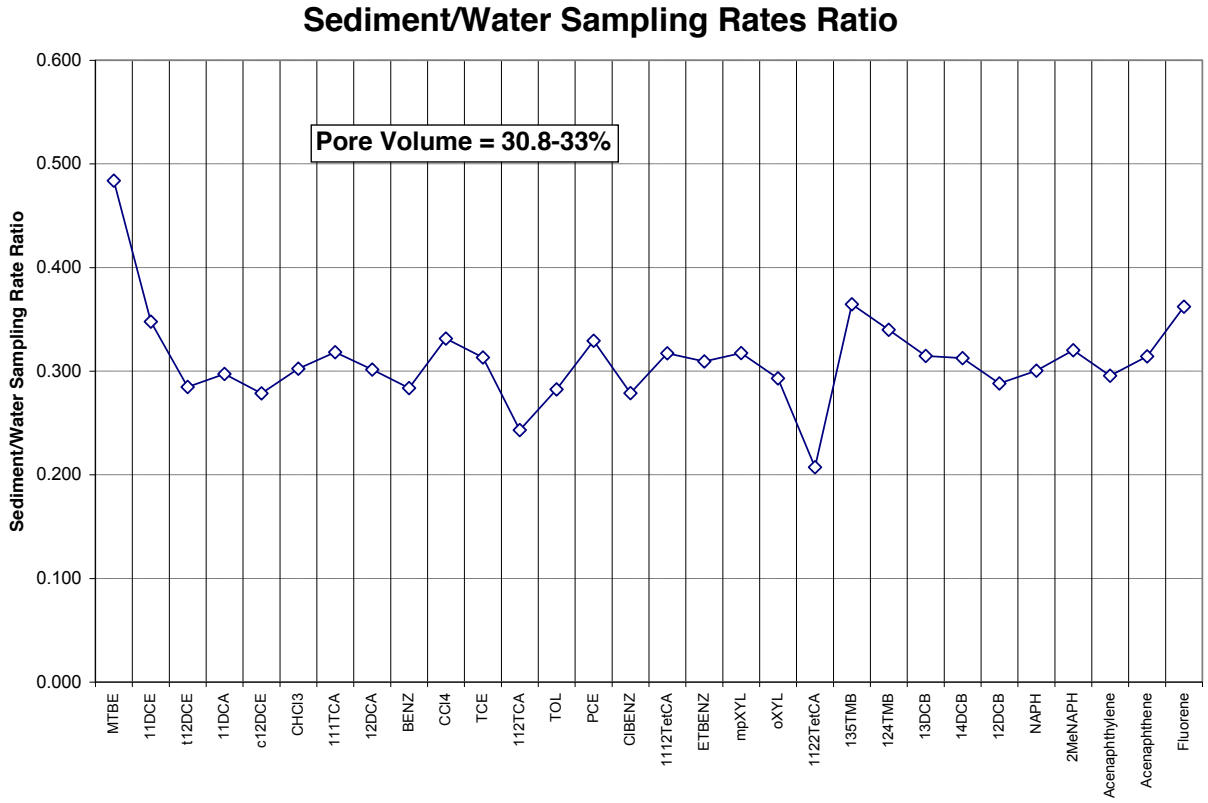
Part 3: Calibration in Sediment

Part 3 describes the effect of sediment solids or sediment pore volume on the sampling rate and concentration measurement.

In sediment, the sampler measures pore water concentration, which is generally agreed to be the preferred measurement as it is more indicative of bioavailability. In sediment the volumetric availability of water to the sampler is reduced by the volume fraction solids in the sediment. As a result sampling rates in sediment are multiplied by the fraction pore water to determine

concentration. Pore water fraction can range from 1.0 for water without sediment to as low as 0.25. Typically most sediments have pore fractions of 0.9 to 0.65.

A sampling rate study was done with water and with water added into a well-packed sorted sand. Pore water fraction in this test was measured between 30.8% and 33% by volume. Below is a plot of the ratio of sampling rates measured in the sediment to open water. The average ratio is equal to the pore water fraction confirming that sampling rate in sediment is on average equal to the product of pore water fraction times the sampling rate in water.



Summary

The AGI Sampler can be used to determine the concentration of volatile and semi-volatile compounds in a water phase. This requires knowing the exposure time and water temperature. It also requires knowing if the sample is above or below 34' of water head and if the water has a velocity above 10 meters/day. Regressions of large amounts of data were used to generate a four constant equation to generate concentration values in water. Potential error in the concentration values is excellent typically less than 25%.

Laboratory Report

Site: Comal & San Marcos Dec 2015
San Antonio, TX

Prepared for:

SWCA Environmental Consultants
6200 UTSA Boulevard
Suite 102
San Antonio, TX
UNITED STATES

Prepared on:
December 31, 2015

Project Summary and Objective

Amplified Geochemical Imaging, LLC. (AGI) provided the AGI Environmental Survey used at:

Comal & San Marcos Dec 2015

San Antonio, TX

The service provided by AGI included delivery of the required quantity of AGI Universal Samplers, analysis by the method described below for the requested organic compounds, reporting of the data, and contour mapping (as needed).

This report includes results for only the samples noted under the Laboratory Sample Report section. If contour maps are part of the project deliverable, the maps will be prepared and issued under a separate report cover, upon receipt of a usable sitemap (electronic) and compound choices for contouring.

Quality Assurance Statement

The AGI Laboratory, at Amplified Geochemical Imaging's facility in Newark, DE USA, operates under the guidelines of its ISO Standard 17025 DoD ELAP accreditation, and its Quality Assurance Manual, Operating Procedures, and Methods (SOP-QA-0462).

For this project, the analytical method, results, and observations reported do [ ] do not [√] fall within the scope of AGI's ISO 17025 accreditation.

Screening/Concentration Method

The AGI Universal Samplers are analyzed at AGI's fixed laboratory using thermal desorption-gas chromatography/mass spectrometry (TD-GC/MS) instrumentation following modified U.S. EPA Method 8260 (SPG-WI-0292) which includes the following:

- **BFB Tuning Frequency:** A BFB tune is analyzed at the start of each analytical run and after every 30 samples.
- **Initial Calibration:** A minimum of a five point calibration curve is analyzed prior to the analysis of samples.
- **Initial Calibration Verification (ICV):** Following the calibration a second-source reference standard is analyzed to verify the accuracy of the calibration. Acceptance criteria for the ICV is +/- 30%.
- **Linearity of Target Compounds:** If the RSD of any target analyte is less than or equal to 25% then average response factor can be used for quantitation. If the RSD exceeds 25% for a target compound a regression equation can be used for quantitation.
- **Continuing Calibration Verification:** After every 10 samples, and at the end of each analytical batch, a mid-level second-source Reference Standard is analyzed. The acceptance criteria for all target analytes in the reference standards are +/- 50% of the true value.
- **Method Blank:** Analyzed prior to the analysis of field samples and every 30 samples.

Note: Analyte levels reported for the field-deployed AGI Universal Samplers that exceed trip and method blank levels, and/or the reporting limit, are more likely to have originated from on-site sources.

Media Sampled:	WATER
Chemist - sample analysis:	Jasmine Smith
Chemist - data processor:	Jasmine Smith
Chemist - data review:	Ian McMullen

Method deviations: None

Please note that data file names ending with R are rerun samples using the second pair of sorbers, in which the original results were not reported. Data file names ending in D are duplicate analysis results for the second set of sorbers from the same sampler, and are reported.

Additional Report Information

- Comments
- Laboratory Sample Report
- Chain of Custody
- Installation and Retrieval Log
- Analytical Results and Key
- Concentration Calculation Method Summary
- Total Ion Chromatograms

Project Specific Comments

None

Survey period [1]	Samplers were installed on December 1, 2015 and retrieved on December 15, 2015 for a sampling period of 14 days.
Tamper seal intact:	Yes
Date received:	12/16/15 11:00 pm By: Clarence W Whigham
COC returned:	Yes

Comments:

Shipment of samplers received by AGI included unused samplers provided to SWCA at an earlier date .

1 - Installation start to end of retrieval, as reported. See installation and retrieval log for individual deployment and retrieval dates and times (i.e., sampler exposure time).

General Comments

Analytical QA/QC

Laboratory instrumentation consists of gas chromatographs equipped with mass selective detectors, coupled with automated thermal desorption units. Sample preparation involves cutting the tip off the bottom of the AGI Universal Sampler, and transferring one or more "sorbers" to a thermal desorption tube for analysis. The insertion/retrieval cord prevents soil, water and other interferences from coming in contact with the adsorbent. No further sample preparation is required. Any replicate sorbers not consumed in the initial analysis will be discarded fifteen (15) days from the date of the laboratory report.

Data are archived and stored in a secure manner as per AGI's Quality Assurance program (SOP-QA-0462).

Total petroleum hydrocarbons (TPH), gasoline-range petroleum hydrocarbons (GRPH), and/or diesel range petroleum hydrocarbons (DRPH), when reported, are calculated using the area under the peaks observed in m/z 55 and 57 selected ion chromatograms. Quantitation of the mass values was performed using the response factor for a specific alkane (present in the calibration standards). TPH values include the entire chromatogram and provide estimates for aliphatic hydrocarbon ranges of C4 to C20. GRPH and DRPH include only the relevant regions of the chromatograms and provide estimates for C4 to C10 and C10 to C20 aliphatic hydrocarbons, respectively.

Trip blanks were provided to document potential exposures that were not part of the signal of interest (e.g., impact during sampler shipment, installation and/or retrieval, and storage). The trip blanks are identically manufactured and packaged AGI Universal Samplers to those samplers deployed in the field . The trip blanks remain unopened during all phases of the project. Levels reported on the trip blanks may indicate potential impact to the samplers other than the contaminant source of interest.

Unresolved peak envelopes (UPEs) are represented as a series of compound peaks clustered together around a central gas chromatograph elution time in the total ion chromatogram. UPEs may be indicative of complex fluid mixtures. UPEs observed early in the chromatograms are considered to indicate presence of more volatile fluids, while UPEs observed later in the chromatogram may indicate the presence of less volatile fluids. Multiple UPEs may indicate the presence of multiple complex fluids.

Total ion chromatograms (TICs) are included in the Attachments. The eight-digit serial number of each sampler is incorporated in the TIC identification (e.g., 12345678.D represents AGI Universal Sampler 12345678).

General Comments

Soil Gas Sampling

For soil gas sampling, the AGI Environmental Survey reports mass levels migrating through the open pore spaces of the soil and diffusing through the sampler membrane for sorption by the engineered, hydrophobic adsorbents, housed within the membrane tube. During the migration of the soil gas away from the source to the AGI Universal Sampler, the vapors are subject to a variety of attenuation factors. The soil gas masses reported on the samplers compare favorably with the concentrations reported in the soil or groundwater (e.g., where soil gas levels are reported at greater levels to other sampled locations on the site, the matrix data should reveal the same pattern, and vice versa). However, due to a variety of factors, a perfect comparison between matrix data and soil gas levels can rarely be achieved.

Soil gas concentrations (µg/m3) are calculated following the method described in the Additional Report Information section.

Soil gas signals reported by this method cannot be correlated specifically to soil adsorbed, groundwater, and /or free-phase contamination. The soil gas signal reported from each AGI Universal Sampler can evolve from all of these sources. Differentiation between soil and groundwater contamination can only be achieved with prior knowledge of the site history (i.e., the site is known to have groundwater contamination only).

Air Sampling

For indoor, outdoor, and crawlspace air sampling, the AGI Environmental Survey reports mass levels present in the air and diffusing through the sampler membrane for sorption by the engineered adsorbents housed within the membrane tube.

Air concentrations (µg/m3) are calculated following the method described in the Additional Report Information section.

Groundwater and Sediment Porewater Sampling

For groundwater and sediment porewater sampling, the AGI Environmental Survey reports the mass levels of compounds present in the water which, when coming in contact with the sampler membrane, partitions out of solution, and diffuses through the sampler membrane for sorption by the engineered adsorbents.

Water concentrations (µg/L) are calculated using the quantified mass, exposure period and the compound specific uptake rate. The rates were measured under controlled experimental conditions. The uptake rates are corrected for water pressure (depth of the AGI Universal Sampler below the water table), water temperature and the aquifer flow rate. For sediment porewater, the uptake rate is corrected for the reduced volume of water in the sediment, by multiplying the uptake rate by the pore water fraction.

SUMMARY OF SAMPLING RATE CALIBRATION FOR AGI UNIVERSAL SAMPLER IN AQUEOUS PHASES

INTRODUCTION:

The Amplified Geochemical Imaging, LLC (AGI) passive vapor sampler is designed to be used for soil gas, water, sediment pore water, and air sampling. This document describes the process used to calibrate the sampler's compound specific sampling or uptake rates in aqueous phases.

Sampling rates are measured following AGI's "Standard Practice for Determining the Sampling Rate of Passive Diffusion Samplers in Various Environmental Media": SPG-SOP-0493. Rates are used to calculate dissolved phase concentrations of volatile and semi-volatile contaminants in water. The calibration process is summarized in three parts: Part 1: shallow water, Part 2: deep water, and Part 3: sediment.

PURPOSE:

The purpose of this document is to:

1. Summarize the test protocol,
2. Summarize the methodology for analysis of data,
3. Present general results for generating concentration calibration of the AGI Universal Sampler

Principle of Operation of the AGI Samper

The AGI Universal Sampler is designed with solid adsorbents enclosed inside a tubular microporous PTFE membrane. When placed in water, the pores and hydrophobic nature of the PTFE keep liquid water from entering the membrane until a water head of about 34 feet is reached. The membrane will not keep water vapor from entering but the adsorbents are very hydrophobic and through testing validated to be unaffected by this moisture vapor. In shallow water, <34', volatile and semi-volatile compounds will partition from the dissolved water into the air phase in the PTFE membrane according to Henry's Law. This partitioning is instantaneous and within seconds-minutes, the compound is adsorbed by the adsorbent inside the sealed tube. Because the diffusivity in air is about 10,000 times higher than the diffusivity in water, the sampling rate is controlled by the water contact area of the membrane that allows the Henry's Law effect to occur. This contact area is set by the membrane diameter and length of the sealed tube, which is fixed in AGI's manufacturing process.

Henry's law as well as diffusivity, which are fundamentally incorporated into the sampling rate, are affected by temperature, T, and follow an Arrhenius equation H_T = Hr x exp([-Ea/R](1/Tr - 1/T)). Because a 5°C temperature change can make a 15% change in sampling rate, the temperature of the sampled water should be known to get the most precise concentration.

The membrane pore size is also small enough that colloidal particles and microbes cannot pass through the membrane. This keeps the adsorbent from getting contaminated and eliminates any need to add preservative or chilling during storage or transportation.

When the water pressure exceeds the water entry pressure of the membrane, about 34 feet of water, the water becomes in contact with the solid adsorbent. Under this condition the compounds in the water will partition from the water into the solid. The partitioning coefficient, K_{AW}, can be approximated by the octanol-water coefficient, K_{OW}, but has been measured more precisely in the lab for AGI's specific solid adsorbent. The sampling rate is the product of the sampling rate at <34' of water and the K_{AW}.

In sediment, the sampler measures pore-water concentration, which is generally agreed to be the preferred measurement as it is more indicative of bioavailability. In sediment the volumetric

availability of water to the sampler is reduced by the volume fraction solids in the sediment, which typically varies from zero to 35%, but can be has high at 73% in well packed and broad particle size distribution sediments. As a result, sampling rates in sediment are multiplied by the fraction pore water in the sediment to determine concentration.

PART 1: Calibration in shallow water

Part 1 summarizes the work in shallow water generating calibration data, evaluating the physical and chemical factors affecting the sampling rate, and measurement of the actual sampling rates or regression calibration equations needed to determine concentrations.

Sample Generation in water

In this calibration work, solutions of analytes at known concentrations were formulated in clean 4 liter smoked glass jugs by injecting microliter measured amounts of environmental standards using a calibrated syringe into pure or deionized water and stirring for a minimum of 2 hours but generally overnight. Headspace in the jugs was minimized and generally less than 1% by volume during the tests. Jugs were temperature controlled by placing them in a water filled cooler, chilled via a cooper tubing loop in the cooler. Temperature was measured with a certified digital temperature gauge and an average value used for each temperature experiment.

AGI samplers were weighted so they won't float and placed in the jugs at time zero. They were removed at various intervals to generate samples along with duplicates that showed mass increasing with exposure time. The sampler exposure time was selected to span minutes to hours and was generally reduced for high concentration tests to maintain uptake with time in roughly the linear dynamic range. Samplers were removed and dried with a paper towel and returned to their original container for analysis. They were analyzed by AGI's 8260C (SPG-WI-318 or SPG-WI-10028) method in duplicate, which is based on EPA SW846 Method 8260C.

Water samples were also taken and measured at an outside accredited lab using EPA SW846 Method 8260B. The concentrations agreed well with the calculated concentrations based on the standard certification, jug volume, and syringe injection. The variability of the outside lab 8260B values were found to be high, so for the sampling rate calculations we used the concentrations based on syringe dosing.

Calibrations were run at five concentrations, nominally at 6, 24, 118, 590, 1420 ug/L and five temperatures nominally at 5, 10, 15, 20, and 25 degrees centigrade. Samples were taken at 4 different exposure times. Samples were run in duplicate. A total of 176 data points were generated using 28 compounds from AGI's standard compounds list. Tridecane and pentadecane were not evaluated due to their very low solubility in water. In addition, another 23 compounds were tested using an 8260 liquid standard at nominal concentrations of 0.5, 1.0, 5.0, 15, 95, and 470 ug/L at a temperature typical of groundwater, 15°C. This is a living calibration and as additional data are generated, they may be qualified and added to this data set to improve the precision of the sampling rate calibration and broaden the compound list.

Key Variable Effects

As expected from theory, at short to moderate exposure times, mass will increase roughly linearly proportional to exposure time, as well as proportional to concentration, and exponentially with temperature following Arrhenius law. Temperature affects the Henry's law as well as diffusivity in water. Sampling rate is generally independent of concentration and time at mass values significantly below saturation. In the following sections we have characterized the sampling rate for each compound as affected by temperature and also developed calibrations using regression which account for the minor impact of time, and mass.

Concentration using Simple Sampling Rate Determination

A simple way to determine concentration is to measure mass on the AGI sampler, divide by exposure time, and divide by sampling rate, SR.

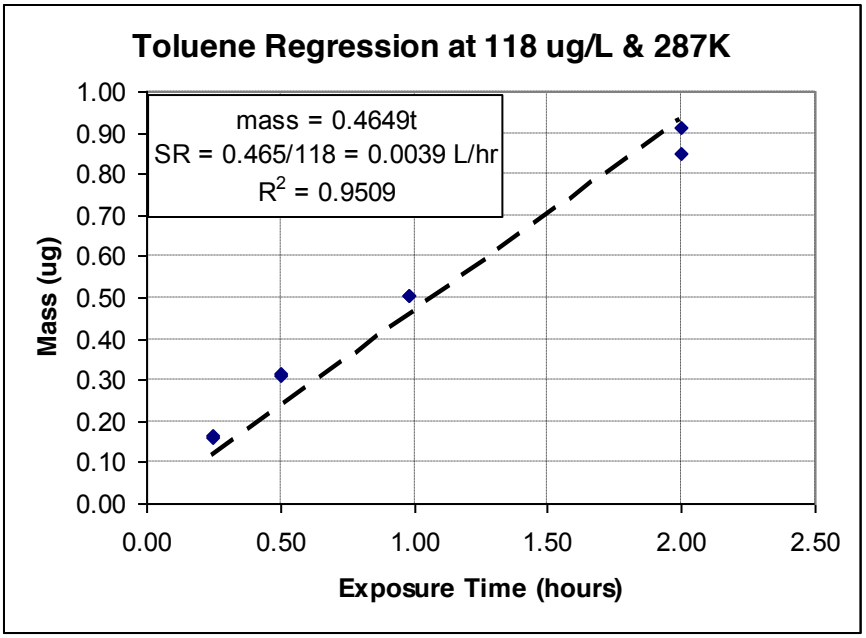
Conc [ug/L] = mass/time/SR (1)

The sampling rate can be determined via measurements of mass versus time at a known concentration and temperature according to the following modification of equation (1).

SR = mass/time/concentration (2)

Sampling rates in L/hr were determined by measuring the trend or regression mass uptake versus time and dividing by the concentration. A measurement like this will use 8 data points (4 times x 2 samples). Such a sampling rate can be measured at any concentration and temperature.

The chart to the right shows a plot of mass versus time for water at 118 ug/L and 287K (actual data from a single run). Slope of 0.465 ug/hr divided by the concentration of 118 ug/L yields a sampling rate, SR, of 0.0039 L/hr.



SR's typically range from about 0.004 to 0.007 L/hr at 15°C. Table A shows SR's measured for our standard compound list at 5 temperatures.

Rigorous Concentration using Regression

A preferred method for determining concentration that will yield improved accuracy over a wide range of concentrations, exposure times, and temperatures is to use all data in a regression analysis, which allows adjustments for the minor non-linear influences of mass and time as well as the effects of temperature. This step is done by regressing equation (1) or a universal version of equation (1):

$$Conc = (mass)^{b} / (time)^{-d} / [-SRo * \exp(-Ea/R/T)] \quad (3)$$

The subtle non-linear effects of mass and time will be evident in the deviation of coefficients b and d from 1.0. This regression generates four constants b, d, SRo, and –Ea/R by regressing ln(conc) versus ln(mass), ln(time), 1/temp. These four constants can be used to determine concentration via the equation:

$$Conc = (mass)^{b} / (time)^{-d} / [-SRo \times \exp(-Ea/R(1/T))] \quad (4)$$

Where conc is in ug/L, mass is in ug, time in hours, T in degrees Kelvin.

Equation (4) an be also expressed at a reference temperature, Tr, such as 15°C by

$$Conc = (mass)^{b} / (time)^{-d} / [-SRr \times \exp(-Ea/R(1/Tr-1/T))] \quad (5)$$

This step allows sampling rates, SRr, at any reference temperature, Tr, and for any analyte to easily be compared. The values of SRr at 293.14K can be found in Table A.

When sampling times are between 0 and 4 hours, using the 4 constant equation (5) is preferred. For concentrations from about 5 to 1500 ug/L one hour exposure times generally give the lowest error, typically with average error of 6-20% and with total error range of 12%-32%. For low concentrations where sampling times are greater than 4 hours, it is preferred to use equation (1) to avoid unrealistic effects from the coefficient d or to set d to 1.0. In such a case SR in equation (1) can be substituted with [SRr x exp(-Ea/R(1/Tr-1/T))] to use an SR representative of the well temperature, T.

The chart to the right is a plot of the calculated concentration from the 4 constant regression compared to the dosed concentration. Agreement is excellent for the 176 data points.

However, there does appear to be a slight high bias of 8.6% over the full range of this data, although it is well within acceptable limits of variability.

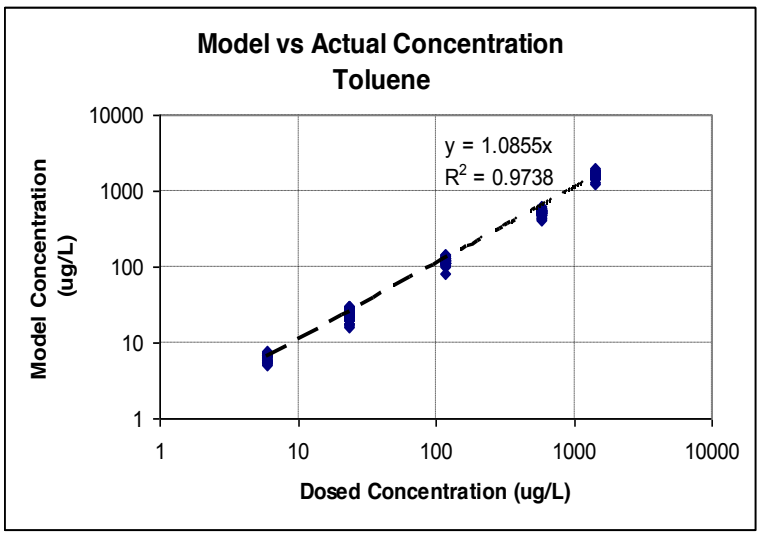


Table B shows the tabulated summary of the 4 constants regression with Rsq values and error estimates for the 4 constants for each analyte. Most regression Rsq values are 0.99 or greater for each analyte. In general, -Ea/R is about 2400+/-400, b is about 0.9, d is about -0.75, and SR(15°C) ranges from .004 L/hr to 0.007 L/hr increasing with MW of the compound.

Error Estimates

The error in the water concentration values will depend on both the error in mass from the analytical method as well as the error in the concentration calibration. Table C shows the error in the mass values from the 8260C low sensitivity method.

The standard error of the regression and standard errors of the constants can be found in table B. For each compound we have measured the error between the derived concentration and the actual concentration. The error tends to be lowest at our recommended exposure time of one hour as shown by the example for Toluene to the right.

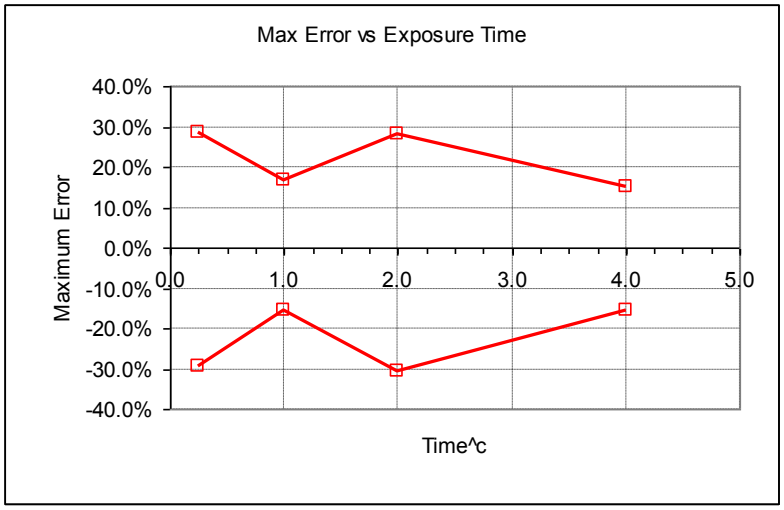

Table D shows the total average error in water concentration by compound as well as the low and high error. The average ranges from about 6% to 20%, which is similar to the analytical method errors. The low and high errors range from 12% to 32% and include contribution from measurement errors in both time and temperature.

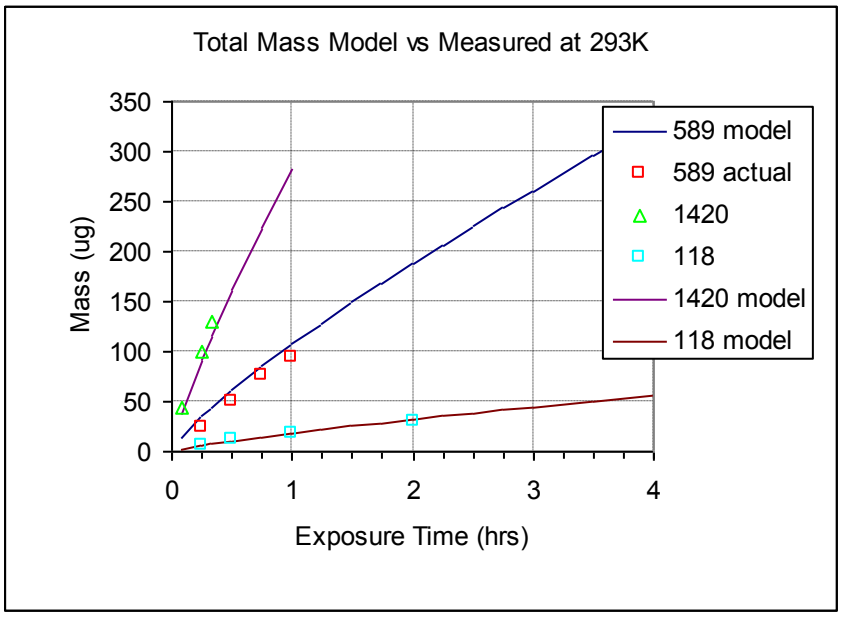
Sorbent Saturation

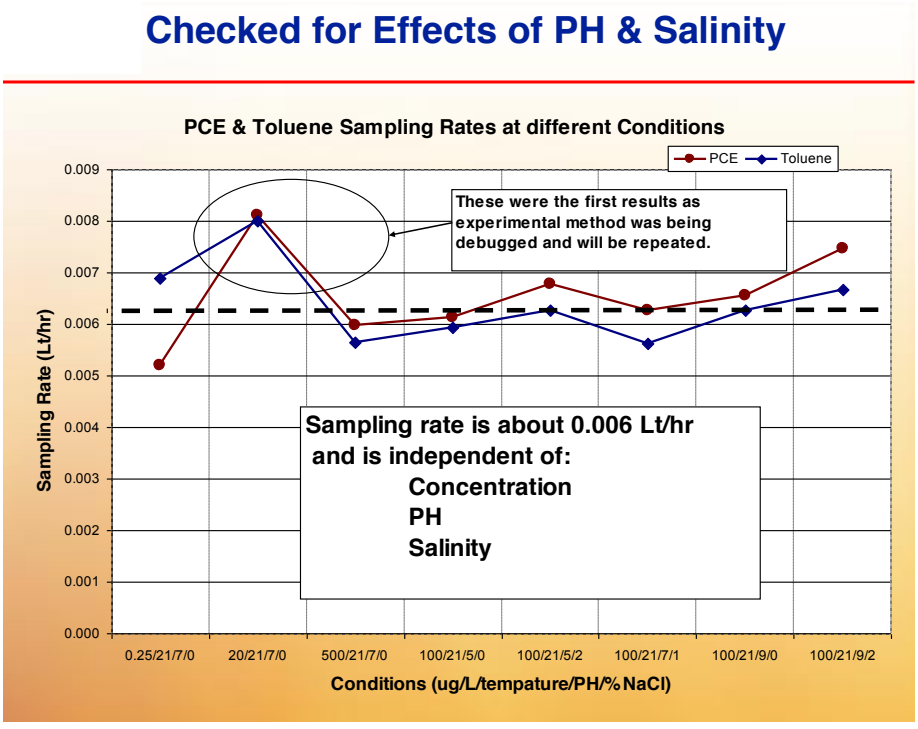
As mass increases on a solid sorbent and approaches saturation, reverse diffusion can occur causing the sampling rate to drop. Eventually the mass level will reach a maximum steady state value at any concentration. A rate of mass uptake with time that deviates significantly from linear, indicates that sorbent saturation could be an issue. When using equation (1), staying in the linear range to avoid the effects of adsorbent saturation is important. We recommend keeping the total mass on the sampler below 50 ug or flagging when this is exceeded.

The 4 constant regression accounts for some of the non linearity allowing good accuracy at higher mass levels. From the experimental data we have found this safe range can be extended to 100 ug or higher as shown in the chart below. This chart compares total mass of all compounds (excluding heavy alkanes, which have solubility issues) versus time in comparison to that predicted from the 4-constant concentration equation.



Effect of PH and Salinity

Because neither PH nor salinity is known to have a significant impact on Henry's law or diffusivity in water, we did not expect them to have a significant impact on sampling rate. To confirm this, experiments were run varying PH from 5 to 9 and NaCl content from 0 to 2%. The chart below shows no significant impact for combinations of PH and NaCl content over this range on the sampling rate of toluene in water at 21°C.

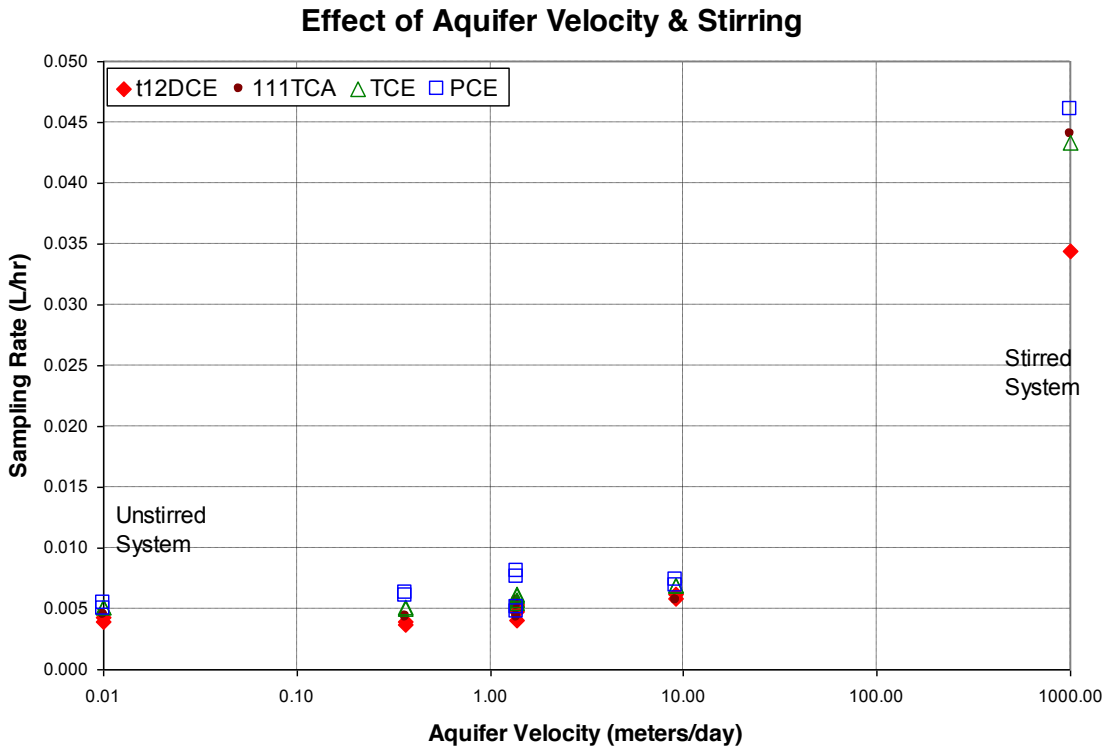


Impact of Aquifer Velocity

The velocity in most aquifers is quite slow, typically a meter/day or less. Occasionally water flow could be much higher such as encountered in karst aquifers, streams or rivers. Mass transfer coefficients are higher in high flow conditions, which will lead to higher sampling rates. We validated that a highly stirred system had sampling rates about 10 times higher than those that were non-stirred. We decided to evaluate the effect of aquifer velocity.

A test apparatus was built comprising a 3" PVC pipe tee filled with clean sand in each of the horizontal straight legs and screened to leave the center open. A test solution was run through this system using a variable flow pump and AGI samplers were placed into the simulated well through the vertical leg of the tee. Tests were run to examine the effect of velocity by varying the pumping rate and hence water velocity.

The chart below shows no significant effect of aquifer velocity up to a speed of about 10 meters/day. At velocities significantly above this, similar to a stirred system, sampling rates are about 10 times higher.

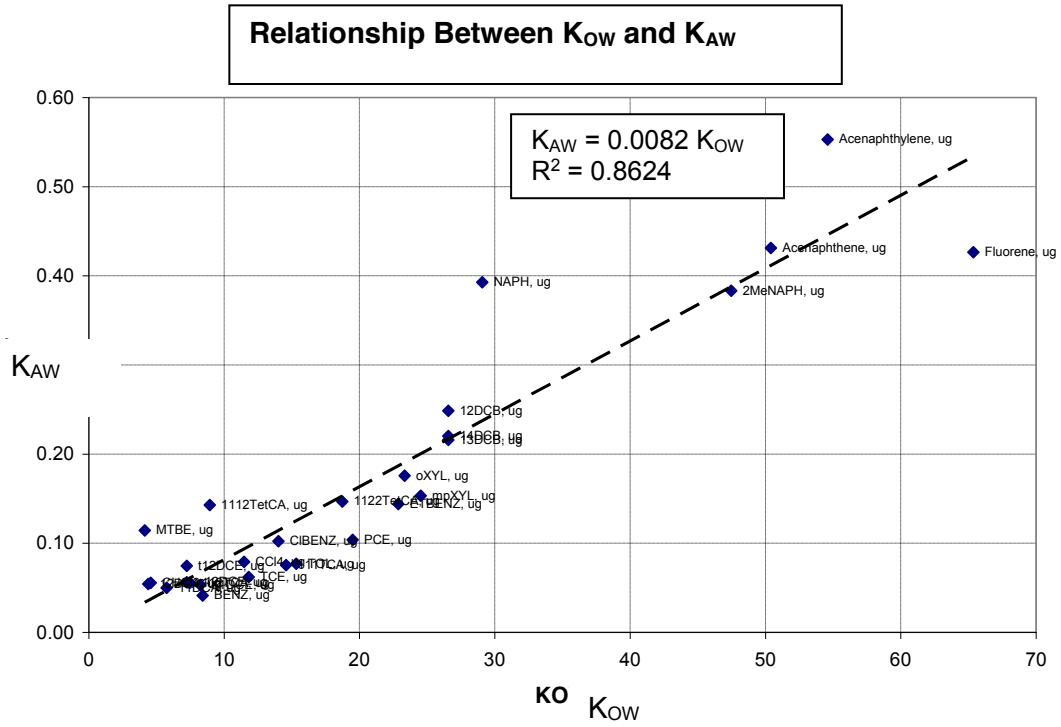


Part 2: Calibration in Deep (>34') water

Part 2 describes the effect of deep water on the AGI sampler and summarizes the effects on sampling rate and concentration measurement.

When the water pressure exceeds the water entry pressure of the membrane, about 34 feet of water, the water becomes in direct contact with the solid adsorbent. Under this condition the compounds in the water will partition from the water into the solid. The portioning coefficient is closely related to the octanol-water coefficient, K_{OW}, but has been measured more precisely in the lab for AGI's specific solid adsorbent, K_{AW}. The sampling rate for deep water is the product of the sampling rate at <34' of water and the K_{AW}.

Measurement of the K_{AW} was done in a one liter stainless steel vessel pressurized with nitrogen to simulate water heads above 34' of water. Pressures of up to 465 psig or 200' of water head were used. The sampling rate change was the same at all pressures above 34' of water. The K_{AW} was determined as the ratio between the mass or sampling rate above 34' of head to the rate at <34' of head and is shown in the chart below.



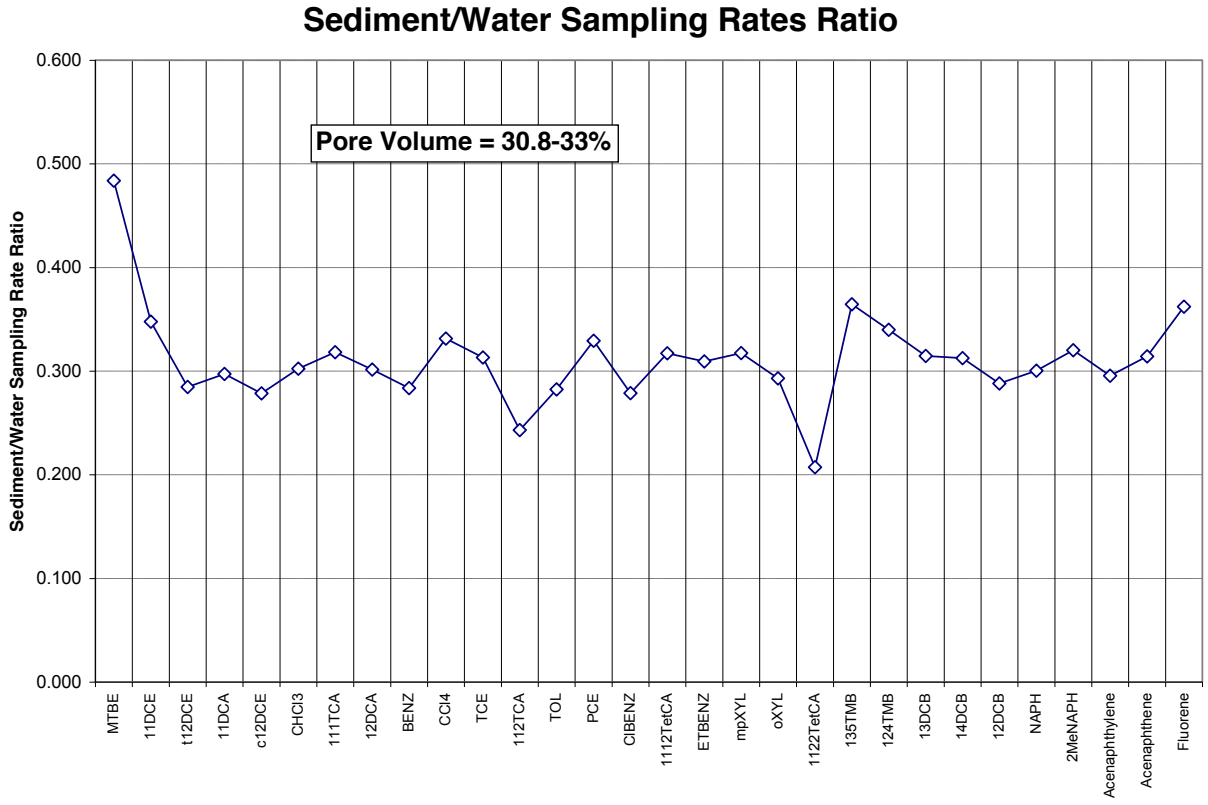
Part 3: Calibration in Sediment

Part 3 describes the effect of sediment solids or sediment pore volume on the sampling rate and concentration measurement.

In sediment, the sampler measures pore water concentration, which is generally agreed to be the preferred measurement as it is more indicative of bioavailability. In sediment the volumetric availability of water to the sampler is reduced by the volume fraction solids in the sediment. As a result sampling rates in sediment are multiplied by the fraction pore water to determine

concentration. Pore water fraction can range from 1.0 for water without sediment to as low as 0.25. Typically most sediments have pore fractions of 0.9 to 0.65.

A sampling rate study was done with water and with water added into a well-packed sorted sand. Pore water fraction in this test was measured between 30.8% and 33% by volume. Below is a plot of the ratio of sampling rates measured in the sediment to open water. The average ratio is equal to the pore water fraction confirming that sampling rate in sediment is on average equal to the product of pore water fraction times the sampling rate in water.



Summary

The AGI Sampler can be used to determine the concentration of volatile and semi-volatile compounds in a water phase. This requires knowing the exposure time and water temperature. It also requires knowing if the sample is above or below 34' of water head and if the water has a velocity above 10 meters/day. Regressions of large amounts of data were used to generate a four constant equation to generate concentration values in water. Potential error in the concentration values is excellent typically less than 25%.

APPENDIX H

ANALYTICAL DATA VALIDATION DISCUSSION

Introduction

This appendix provides an overview of the SWCA's post analyses review of the Eurofins/Calscience (Calscience), San Antonio River Authority (SARA), and Amplified Geochemical Imaging, LLC (AGI) analytical data set. In general, the data are considered valid for the intended purpose of assessing the baseline of sediment quality, stormwater runoff quality, surface water (under base flow conditions) and passive diffusion samplers (PDS) at a screening level for Comal and San Marcos Springs. Analyses with any associated laboratory issues are listed herein.

Worth noting in this assessment are the detection of plasticizer compounds such as bis(2-ethylhexyl) phthalate (DEHP) and other phthalate compounds. While it is possible these compounds were introduced post-sample collection from either sampling equipment, or laboratory equipment, they should not be completely dismissed.

Based on analysis of 2013 laboratory data, the EAA concluded that three compounds detected in sediment samples may have been laboratory artifacts. The compounds were DEHP, di-n-octyl phthalate, and di-n-butyl phthalate. The EAA noted in the 2013 *Edwards Aquifer Habitat Conservation Plan Expanded Water Quality Report* that as the data set grows, additional conclusions could be drawn. The 2014 laboratory analyses of sediment samples did not detect di-n-octyl phthalate or di-n-butyl phthalate. However, DEHP was detected in three of the sediment samples in 2014 (HSM320, HSM330, and HSM350). DEHP was also detected in the three of the 2015 sediment samples (HSM340, HSM350, and HSM360).

DEHP was not detected in the laboratory method blank or trip blank, and a different laboratory and sampling equipment was used by SWCA. Therefore, it appears DEHP is present within sediment samples in the middle reaches of the San Marcos Spring complex. Future analyses may help better understand the possible presence of DEHP within sediments in both Comal and San Marcos Spring complexes.

Analytical results are discussed by analytical laboratory sample data group number, and by sample event type and date. Each event (surface water/base flow, stormwater, PDS, or sediment) is discussed by sample data group with sample names and date outlined for each event in the beginning of the discussion.

A key to sample names is provided below:

Key to Sample Names

H CS 1 10

H=HCP
CS=Comal Springs (**SM**=San Marcos Springs)
1=Sample Type (1=Surface Water, 2=Storm, 3=Sediment, 4=PDS)
10=Sample Location
Field Duplicates are identified with the prefix FD followed by the sample identification described above. Trip Blank samples are denoted with the prefix "TB" followed by a sequential number. Equipment Blank samples are denoted with the prefix "EB" followed by a sequential number.

Corrective Action Comments

The two following bulleted items describe corrective actions from 2014 that were effective in at reducing problems:

- TPH was consistently detected in PDS Trip Blanks from AGI. AGI had provided an annual supply of PDS. SWCA returned unused PDS and requested separate, new batches of PDS for the December 2014 and each individual 2015 sampling event.

- Calscience packaged three VOA vials within a tight zip-lock bag within a bubble wrap pouch. Frequently, some of the VOA vials broke during return shipping. During the last two sampling events of 2014 and all events of 2015, SWCA individually wrapped the VOA vials as opposed to having the three vials packaged together.

Analytical Data Review Summary for HCP samples collected in 2015.

Data Group Numbers **(HCP surface water/base flow samples collected March 16, 2015, and March 25, 2015, Comal and San Marcos springs):**

15-03-1281-1 (HCS 110)
15-03-1281-2 (HCS 120)
15-03-1281-3 (HCS 130)
15-03-1281-4 (HCS 140)
15-03-1281-5 (HCS 160)
15-03-1281-6 (FDHCS 120)
15-03-1281-7 (Trip Blank 02)

15-03-2020-1 (HSM 110)
15-03-2020-2 (HSM 120)
15-03-2020-3 (HSM 130)
15-03-2020-4 (HSM 140)
15-03-2020-5 (HSM 150)
15-03-2020-6 (HSM 160)
15-03-2020-7 (HSM 170)
15-03-2020-8 (FDHSM110)
15-03-2020-9 (Trip Blank 04)

General Comments

Although some analytical issues are noted for the data group, unless otherwise noted in the detailed discussion, the data are considered valid for the purposes of the investigation. pH values are collected in the field at the time of sample collection and are listed in the field parameters for each sample event. As such, the laboratory pH values which are flagged for hold time exceedances are not used for sample assessment purposes.

Trip Blanks

There were no detections in the trip blanks associated with this sample set.

QA/QC Discussion – Comal and San Marcos Springs Surface/Base Flow Samples (Sampled March 16, 2015 and March 25, 2015)

Issues associated with work order 15-03-1281

Magnesium was detected in the Method Blank associated with all of the Comal surface samples at a level of 0.00760 J mg/L. The detected concentration is below the Reporting Limit, but above the Method Detection Limit. It was therefore "J" flagged. Due to the low concentration and lack of concerns with magnesium concentrations in the subject samples, the results are accepted.

Method EPA 365.1 (Batch No. 150323LO1) – Recovery of matrix spike (MS) and matrix spike duplicates (MSD) were outside of control limits due to suspected matrix interference for total phosphorous. The associated Laboratory Control Sample (LCS) was in control; therefore, the results are accepted.

Method SM 5310 B (Batch No. F0326DOCS1) – Recovery of the MSD compound was outside of control limits due to suspected matrix interference for dissolved organic carbon (DOC). The associated Laboratory Control Sample (LCS) was in control; therefore, the results are accepted.

Method EPA 6010B (Batch No. 150330SA2) - For analytes calcium, magnesium, sodium, and silicon, spike recovery and relative percent difference (RPD) control limits do not apply—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted.

Method EPA 6020 (Batch No. 150319SA1) – Recovery of the MS and MSD were outside of control limits due to suspected matrix interference for aluminum. The associated LCS was in control; therefore, the results are accepted. The recovery of the pulse digestion spike was also out of controls for aluminum due to suspected matrix interference. The result was biased high, the result is accepted.

Issues associated with work order 15-03-2020

Magnesium was detected in the Method Blank at a level of 0.0449 J mg/L. The detected concentration is below the Reporting Limit, but above the Method Detection Limit. It was therefore "J" flagged. Due to the low concentration and lack of concerns with magnesium concentrations in the subject samples, the results are accepted.

Method EPA 6010B (Batch No. 150327SA4A) - For analytes calcium, magnesium, and silicon, spike recovery and RPD control limits do not apply—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted.

Data Group Numbers **(HCP surface water/base flow samples collected September 9 and 17, 2015, Comal and San Marcos springs):**

15-09-0733-1 (HCS 110)
15-09-0733-2 (HCS 120)
15-09-0733-3 (FDHCS 120)
15-09-0733-4 (HCS 130)
15-09-0733-5 (HCS 140)
15-09-0733-6 (HCS 160)
15-09-0733-7 (Trip Blank 11)

15-09-1440-1 (HSM 110)
15-09-1440-2 (FDHSM 110)
15-09-1440-3 (HSM 120)
15-09-1440-4 (HSM 130)
15-09-1440-5 (HSM 140)
15-09-1440-6 (HCS 150)
15-09-1440-7 (HSM 160)
15-09-1440-8 (HSM 170)
15-09-1440-9 (Trip Blank 12)

General Comments

Although some analytical issues are noted for the data group, unless otherwise noted in the detailed discussion, the data are considered valid for the purposes of the investigation. pH values are collected in the field at the time of sample collection and are listed in the field parameters for each sample event. As such, the laboratory pH values which are flagged for hold time exceedances are not used for sample assessment purposes.

Trip Blank (Comal and San Marcos)

Trip Blank (TB11) associated with this sample set had a detection of 0.25 J ug/L for toluene. This constituent was not detected in the subject samples.

QA/QC Discussion – Comal and San Marcos Springs Surface/Base Flow Samples (Sampled September 9 and 17, 2015)

Issues associated with work order 15-09-0733

Calcium, magnesium, potassium and sodium were detected in the Method Blank associated with all of the Comal surface samples. The detected concentrations are below the Reporting Limits, but above the Method Detection Limits. They were therefore "J" flagged. Due to the low concentration and lack of concerns with these analyte concentrations in the subject samples, the results are accepted.

Method EPA 300.0 (Batch No. 150910S01) – Recovery of the MS and MSD were outside of control limits due to suspected matrix interference for chloride and sulfate. The associated LCSs were in control; therefore, the results are accepted.

Method EPA 365.1 (Batch No. 150915S01) – Recovery of the MS and MSD were outside of control limits due to suspected matrix interference for total phosphorous. The associated LCS was in control; therefore, the results are accepted.

Method EPA 6010B (Batch No. 150911SA5) - For analytes calcium, magnesium, and silicon, spike recovery and relative percent difference (RPD) control limits do not apply—resulting from the parameter

concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted.

Method EPA 8141A (Batch No. 150911L03) – LCS and LCSD percent recoveries were out of control for merphos. This compound was not detected in the subjected samples. The results could be biased high; therefore, the results are accepted.

Method 1694 - Caffeine analysis was subcontracted to ALS Environmental by Calscience. The subcontracted laboratory received less than optimal sample volume which resulted in elevated detection limits. In the future, adequate sample volume will be provided to ALS Environmental by Calscience.

Issues associated with work order 15-09-1440

Magnesium was detected in the Method Blank associated with all of the San Marcos surface samples. The detected concentration, 0.00711 mg/L, is below the Reporting Limit, but above the Method Detection Limit. The result is therefore "J" flagged. Due to the low concentration and lack of concerns with this analyte in the subject samples, the results are accepted.

Method EPA 300.0 (Batch No. 150918S01) – Recovery of the MS and MSD were outside of control limits due to suspected matrix interference for nitrate and sulfate. The associated LCSs were in control; therefore, the results are accepted.

Method EPA 365.1 (Batch No. 151002S01) – Recovery of the MS and MSD were outside of control limits due to suspected matrix interference for nitrate and sulfate. The associated LCSs were in control; therefore, the results are accepted.

Method EPA 6010B (Batch No. 150922SA6A) - For analytes calcium, magnesium, and silicon, spike recovery and relative percent difference (RPD) control limits do not apply—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted.

Method EPA 6020 (Batch No. 150922SA3A) - For manganese, spike recovery and relative percent difference (RPD) control limits do not apply to the MS, MSD or pulse digestion spike samples—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted.

Method EPA 6010B (Batch No, 150922LA6F) – The LCS percent recovery was out of range for silicon. Results may be biased low but are accepted.

Method EPA 8141A (Batch No. 150124L03) – LCS and LCSD percent recoveries were out of control for merphos. This compound was not detected in the subjected samples. The results could be biased high; therefore, the results are accepted.

Data Group Numbers **(HCP stormwater samples collected January 22-23, 2014, at Comal Springs):**

15-01-1404-1 (HCS 210 Lead)
15-01-1404-2 (HCS 240 Lead)
15-01-1404-3 (HCS 250 Lead)

15-01-1511-12 (FDHCS 270 Trail)
15-01-1511-13 (Trip Blank 1)

General Comments

Although some analytical issues are noted for the data group, unless otherwise noted in the detailed discussion, the data are considered valid for the purposes of the investigation. pH values are collected in the field at the time of sample collection and are listed in the field parameters for each sample event. As such, the laboratory pH values which are flagged for hold time exceedances are not used for sample assessment purposes.

All samples were collected outside of laboratory operating hours. Therefore all *E. coli* samples were analyzed outside of their hold times. The initial blank for *E. coli* was also analyzed outside of hold times for batch E_COLI_QUANTITRAY-41482 associated with samples HCS 250 Trail, HCS 260 Trail, HCS 270 Trail, FDHCS 260 Trail and FDHCS 270 Trail.

Trip Blank

There were no detections in the trip blank associated with these samples.

QA/QC Discussion – Comal Springs Stormwater Samples (Sampled January 22-23, 2015)

Issues associated with all January 2015 stormwater samples

Magnesium was detected at a concentration of 0.0522 J mg/L in batch 150126L6FF within the Method Blank, which is below the Reporting Limit, but above the Method Detection Limit. It was therefore "J" flagged. Due to the low concentration and lack of issues with magnesium concentrations in the subject samples, the results are accepted.

Method EPA 6010B (Batch No. 150126SA6) - For analytes calcium and magnesium, spike recovery and RPD control limits do not apply—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted.

Method EPA 6010B (Batch No. 150126L6FF) – Percent recovery of silicon in the LCS was outside of the control limit and results may be biased low. Due to lack of issues with silicon concentrations in the subject samples, the results are accepted.

Issues specific to work order 15-01-1404

Method EPA 365.1 (Batch No. 150202SO1) – Recovery of the MS and MSD were outside of control limits due to suspected matrix interference for total phosphorous. The associated LCS was in control; therefore, the results are accepted.

Method EPA 8141A (Batch No. 150124L03) – LCS and LCSD percent recoveries were out of control for merphos. This compound was not detected in the subjected samples. The results could be biased high; therefore, the results are accepted.

Issues specific to individual samples

HCS 260 Trail Method EPA 8082 – Recovery of the surrogate compounds was outside of control limits. Results may be biased high; however, no compounds were detected in the sample and the method blank surrogate recovery was in control. The results are accepted.

Data Group Numbers **(HCP stormwater samples collected May 5-6, 2015, at San Marcos springs):**

15-05-0402-24 (FDHSM 230 Trail)
15-05-0402-25 (FDHSM 231 Trail)

General Comments

Although some analytical issues are noted for the data group, unless otherwise noted in the detailed discussion, the data are considered valid for the purposes of the investigation. pH values are collected in the field at the time of sample collection and are listed in the field parameters for each sample event. As such, the laboratory pH values which are flagged for hold time exceedances are not used for sample assessment purposes. All samples were collected outside of laboratory operating hours. Therefore all *E. coli* samples were analyzed outside of their hold times.

Trip Blanks

There were no detections in the trip blank associated with these samples.

QA/QC Discussion – San Marcos Springs Stormwater Samples (Sampled May 5 and 6, 2015)

Issues associated with specific batches of stormwater samples

Method EPA 6010B (Batch No. 150507LA6A) - Magnesium was detected in the Method Blank at a level of 0.00476 J mg/L. The detected concentration is below the Reporting Limit, but above the Method Detection Limit. It was therefore "J" flagged. Due to the low concentration and lack of concerns with magnesium concentrations in the subject samples, the results are accepted.

Method EPA 365.1 (Batch No. 150520S01) – Recovery of the MS and MSD compound was outside of control limits due to suspected matrix interference for total phosphorous. The associated LCS was in control; therefore, the results are accepted.

Method EPA 6010B (Batch No. 150507SA5) - For analytes calcium, magnesium, and silicon, spike recovery and RPD control limits do not apply—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted.

Method EPA 6010B (Batch No. 150507SA6) - For analytes calcium, magnesium, and silicon, spike recovery and RPD control limits do not apply—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted. Recovery of the MS and MSD compound was out of control due to suspected matrix interference for strontium. The results may be biased high; however, the LCS was in control and the results are accepted.

Method EPA 6020 (Batch No. 150507SA4) – The MS/MSD percent difference was out of control due to suspected matrix interference for antimony, arsenic, beryllium, cadmium, chromium, copper, lead, nickel, selenium, thallium, and zinc. Recovery of the MS compound was outside of control limits due to suspected matrix interference for cadmium. The associated LCS was in control; therefore, the results are accepted.

Samples HSM 270 Trail, FDHSM 210 Trail, FDHSM 230 Trail, and FDHSM 231 Trail Method EPA 6020 (Batch No. 150507LA6F) - Arsenic was detected in the Method Blank at a level of 0.000469 J mg/L. The detected concentration is below the Reporting Limit, but above the Method Detection Limit. It was therefore "J" flagged. The detections in these results are similar to the levels detected in the Lead and Peak samples. However, none of the other trail samples had arsenic detections. These results may be biased high but are within the range of results in the unaffected samples. Results are accepted.

Method SM 6020 (Batch No. 150507SA6) – Recovery of the MSD compound was outside of control limits due to suspected matrix interference for antimony, arsenic, and cadmium. The associated LCS was in control; therefore, the results are accepted.

Method EPA 8260B (Batch No. 150515S020) – The MS/MSD percent difference was out of control due to suspected matrix interference for methyl-t-butyl ether (MTBE). MS and MSD percent recoveries both in acceptable range, therefor the results are accepted.

Method EPA 8260B (Batch No. 150518S007) – Recovery of the MSD compound was outside of control limits due to suspected matrix interference for carbon tetrachloride and 1,1-dichloroethene. The associated LCS was in control; therefore, the results are accepted.

Issues specific to individual samples

HSM 240 Peak Method EPA 8081A – Recovery of one surrogate compound was outside of control limits. Results may be biased low. The method blank surrogate recovery was in control. The results are accepted.

HSM 230 Lead Method EPA 8141A – Recovery of the surrogate compound was outside of control limits. Results may be biased high; however, no compounds were detected in the sample and the method blank surrogate recovery was in control. The results are accepted.

15-10-1995-19 (FDHSM 230 Trail)
15-10-1995-20 (FDHSM 231 Trail)

General Comments

Although some analytical issues are noted for the data group, unless otherwise noted in the detailed discussion, the data are considered valid for the purposes of the investigation. pH values are collected in the field at the time of sample collection and are listed in the field parameters for each sample event. As such, the laboratory pH values which are flagged for hold time exceedances are not used for sample assessment purposes. Because sample collection occurred late in the day on a Friday, samples could not be packaged and delivered to FedEx in time for a Saturday delivery. Therefore, samples associated with work order 15-10-1995 were held on ice at SWCA over the weekend and shipped to the laboratory Monday, October 26, 2015. This resulted in the nitrate samples from this work order being received outside of hold times.

The majority of samples were collected outside of laboratory operating hours. Therefore many *E. coli* samples were analyzed outside of their hold times. In addition, *E. coli* sample HSM230 Lead contained limited air space and samples HCS260 Peak, HSM231 Lead and FDHSM230 Trail contained limited sample volume.

High sample concentrations of caffeine required that samples HCS210 Lead and HCS250 Lead be diluted for effective analysis.

Trip Blank

There were no detections in the trip blanks associated with these samples.

QA/QC Discussion – Comal and San Marcos Springs Stormwater Samples (Sampled October 23, 2015)

Issues specific to work order 15-10-1856

Method EPA 365.1 (Batch No. 151109S02) – Recovery of the MS and MSD were outside of control limits due to suspected matrix interference for total phosphorous. The associated LCS was in control; therefore, the results are accepted.

Method SM 5310 B (Batch No. F1105TOCS1) – Recovery of the MS and MSD were outside of control limits due to suspected matrix interference for total organic carbon. The associated LCS was in control; therefore, the results are accepted.

Method EPA 6010B (Batch No. 151026SA4A) - For analytes calcium, magnesium, and silicon spike recovery and RPD control limits do not apply—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted.

Method EPA 6020 (Batch No. 151026SA1) – The MS/MSD RPD was out of control for nickel due to suspected matrix interference. The MS and MSD were each within control. Recovery of the MS for aluminum was below the control due to suspected matrix interference. Spike recovery and RPD control limits do not apply for manganese for the MS, MSD or pulse digestion spike samples due to the sample concentration exceeding the spike concentration by a factor of four or greater. The results are accepted.

Issues specific to work order 15-10-1995

Method 6010B (Batch No. 151028LA8F)- Calcium was detected in the Method Blank at a level of 0.0244 J mg/L. The detected concentration is below the Reporting Limit, but above the Method Detection Limit. It was therefore “J” flagged. Due to the low concentration and lack of concerns with calcium concentrations in the subject samples, the results are accepted.

Method 6020 (Batch No. 151028LA5F)- Zinc was detected in the Method Blank at a level of 0.00185 J mg/L. The detected concentration is below the Reporting Limit, but above the Method Detection Limit. It was therefore “J” flagged. Due to the low concentration and lack of concerns with zinc concentrations in the subject samples, the results are accepted.

Method EPA 300.0 (Batch No. 151031S01) – Recovery of the MS and MSD were outside of control limits due to suspected matrix interference for sulfate. The associated LCS was in control; therefore, the results are accepted.

Method EPA 365.1 (Batch No. 151110S01) – Recovery of the MS and MSD were outside of control limits due to suspected matrix interference for total phosphorous. The associated LCS was in control; therefore, the results are accepted.

Method EPA 365.1 (Batch No. 151110S02) – Recovery of the MS and MSD were outside of control limits due to suspected matrix interference for total phosphorous. The associated LCS was in control; therefore, the results are accepted.

Method SM 5310 B (Batch No. F1109TOCS2) – Recovery of the MS and the MS/MSD RPD were outside of control limits due to suspected matrix interference for total organic carbon. The associated LCS was in control; therefore, the results are accepted.

Method EPA 6010B (Batch No. 151028SA8) – For analytes calcium, magnesium, and silicon spike recovery and RPD control limits do not apply—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted.

Method EPA 6010B (Batch No. 151028SA9) - For analytes calcium, magnesium, and silicon spike recovery and RPD control limits do not apply—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted.

Method EPA 6020 (Batch No. 151028SA4) – Recovery of the MS and MSD were outside of control limits due to suspected matrix interference for zinc. The associated LCS was in control; therefore, the results are accepted.

Method EPA 6020 (Batch No. 151026SA1) – The MS/MSD RPD was out of control for selenium due to suspected matrix interference. The MS and MSD were each within control. The results are accepted.

Method EPA 8260B (Batch No. 151030S009) – Recovery of the MS and MSD were outside of control limits due to suspected matrix interference for vinyl chloride. The associated LCS was in control; therefore, the results are accepted.

Method EPA 6020 (Batch No. 151028SA4) – Recovery of the pulse digestion spike was outside of control limits due to suspected matrix interference for selenium. All detections were below the reporting limit and two orders of magnitude lower than the regulatory standard used for result comparison (MCL); therefor, the results are accepted.

Method EPA 6020 (Batch No. 151028SA5) – Recovery of the pulse digestion spike was outside of control limits due to suspected matrix interference for selenium. All detections were below the reporting limit and two orders of magnitude lower than the regulatory standard used for result comparison (MCL); therefor, the results are accepted.

Issues specific to individual samples

HCS 260 Trail Method EPA 8082 – Recovery of a surrogate compound was above the acceptance limit. Results may be biased high; however, no compounds were detected in the sample and the method blank surrogate recovery was in control. The results are accepted.

HSM 260 Trail Method EPA 8151A – Recovery of the surrogate compound was above the acceptance limit. Results may be biased high; however, no compounds were detected in the sample and the method blank surrogate recovery was in control. The results are accepted.

FDHSM 210 Trail Method EPA 8151A – Recovery of the surrogate compound was above the acceptance limit. Results may be biased high; however, no compounds were detected in the sample and the method blank surrogate recovery was in control. The results are accepted.

HSM 270 Peak Method EPA 8151A – Recovery of the surrogate compound was above the acceptance limit. Results may be biased high; however, no compounds were detected in the sample and the method blank surrogate recovery was in control. The results are accepted.

15-06-0567-9 (Trip Blank 08)
15-06-0567-10 (Equipment Blank 01)

General Comments

Although some analytical issues are noted for the data group, unless otherwise noted in the detailed discussion, the data are considered valid for the purposes of the investigation. Samples were collected in glass jars using stainless steel trowels. The water depth and sediment availability at HCS 330 made collection with a trowel impossible. The HCS 330 sample was collected in a plastic sleeve using a hand core sampler and extruded into the glass sample jars.

Trip Blanks

There were no detections in the trip blanks associated with these samples.

Equipment Blanks

Two equipment blanks were collected. One sample was collected by pouring ASTM Type II Reagent Grade water over a decontaminated trowel. The second sample was collected by pouring ASTM Type II Reagent Grade water through a new sample tube. There were several compounds detected in both of the two equipment blanks. The detections are similar between each blank despite the differences in sampling equipment. SWCA suspects that the detected compounds were present in the ASTM Type II Reagent Grade water used. The plastic sample tube was a new, single-use tube from the box and was therefore not decontaminated, eliminating decontamination procedures as the source of interference. Many of the detections were "J" flagged and substantially lower than the levels detected in the sediment samples. Therefore, the equipment blank analyses results are not anticipated to have affected the usability of results of the sediment sample analyses. The equipment blank detections are summarized in Table 1.

Table 1. Detections in sediment equipment blanks June 2015

Sample	Associated Equipment	Date Collected	Calcium mg/L	Magnesium mg/L	Sodium mg/L	Barium mg/L	Copper mg/L	Nickel mg/L	Zinc mg/L	Manganese mg/L	Chloroform µg/L	Toluene µg/L	Carbon, Total Organic mg/L	Phosphorous, Total mg/L

QA/QC Discussion – Comal and San Marcos Springs Sediment Samples (Sampled June 4, and 5, 2015)

Issues associated with work order 15-06-0463

Method EPA 300.0 (Batch No. 150610S01P) – Recovery of the MS and MSD compound was outside of control limits due to suspected matrix interference for fluoride. The associated LCS was in control; therefore, the results are accepted.

Method EPA 6010B (Batch No. 150610S04) - For analytes calcium, magnesium, potassium and silicon, spike recovery and RPD control limits do not apply—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted.

Method EPA 6020 (Batch No. 150608S01) - For analytes barium, aluminum, iron and manganese, spike recovery and RPD control limits do not apply—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted.

Method SM 8270C (Batch No. 150613S07) – Recovery of the MS and MSD compound was outside of control limits due to suspected matrix interference for 1,4-dichlorobenzene and 1,2,4-trichlorobenzene. The associated LCS was in control; therefore, the results are accepted.

Method SM 8260B (Batch No. 150613S007) – Recovery of the MS and/or MSD compound was outside of control limits due to suspected matrix interference for benzene, bromodichloromethane, carbon disulfide, chloroform, 1,1-dichloroethene, c-1,2-dichloroethene, t-1,2-dichloroethene, 1,2-dichloropropane, c-1,3-dichloropropene, methylene chloride, toluene, 1,1,1-trichloroethane and trichloroethene. The associated LCS was in control; therefore, the results are accepted.

Method EPA 6020 (Batch No. 150608L01) – LCS recovery percentage was in the Marginal Exceedance (ME) control limit range for iron. This method allows for one ME result; therefore, results are accepted.

Method EPA 8260B (Batch No. 150607L024) – LCS recovery percentage was in the Marginal Exceedance (ME) control limit range for 1,2-dichloroethane. This method allows for one ME result; therefore, results are accepted.

Issues associated with work order 15-06-0463

Method EPA365.1 (Batch No. 150613S01) - Recovery of the MS and MSD compound was out of control due to suspected matrix interference for total phosphorous. The results may be biased high; however, the LCS was in control, and the results are accepted.

Method EPA 6010B (Batch No. 150611S09A) - For analytes calcium, magnesium, and silicon, spike recovery and RPD control limits do not apply—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Recovery of the MS and/or MSD compound was out of control due to suspected matrix interference for potassium, sodium, and strontium. The results may be biased high; however, the LCS was in control, and the results are accepted.

Method EPA 6010B (Batch No. 150615SA4) - For analytes calcium, magnesium, sodium and silicon, spike recovery and RPD control limits do not apply—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted.

Method EPA 6020 (Batch No. 150612S01) - For analytes barium, aluminum, iron, and manganese spike recovery and RPD control limits do not apply—resulting from the parameter concentration in the sample exceeding the spike concentration by a factor of four or greater. Results are accepted.

Method EPA 8260B (Batch No. 150608S026) – Recovery of the MS and MSD compound was outside of control limits due to suspected matrix interference for 1,2-dibromoethane, 1,2-dichloroethane, p/m-xylene, and o-xylene. The associated LCS was in control; therefore, the results are accepted.

Method EPA 8260B (Batch No. 150608S015) – Recovery of the MS and/or MSD compound was outside of control limits due to suspected matrix interference for benzene, chlorobenzene, 1,2-dibromoethane, 1,2-dichloroethane, toluene, p/m-xylene, and o-xylene. The associated LCS was in control; therefore, the results are accepted.

Issues specific to individual samples

EB01 Method 6010B - Magnesium was detected in the Method Blank at a level of 0.0372 J mg/L. The detected concentration is below the Reporting Limit, but above the Method Detection Limit. It was therefore "J" flagged. Due to the low concentration and lack of concerns with magnesium concentrations in the subject samples, the results are accepted.

HSM 350 Method EPA 8081A – Recovery of the surrogate compounds were outside of control limits. Results may be biased high; however, no compounds were detected in the sample and the method blank surrogate recovery was in control. The results are accepted.

Data Group Numbers **(HCP PDS deployed February 3 – February 17, 2015, at Comal and San Marcos springs):**

HCS 410 ***00755224***	HSM 410 ***00755230***
HCS 420 ***00755225***	HSM 420 ***00755231***

	HSM 460 ***00755236***
Trip Blank 02 ***00755228***	HSM 470 ***00755237***

General Comments

Although some analytical issues are noted for the data group, unless otherwise noted in the detailed discussion, the data are considered valid for the purposes of the investigation. PDSs were deployed from February 3, 2015, through February 17, 2015. The initial method blank data was accidentally overwritten by the laboratory and not available for inclusion in the laboratory report. However, there was no evidence of system contamination observed in any other quality control sample; the results are accepted.

Trip Blanks

There were no detections in the trip blank associated with these samples.

Equipment Blanks

Equipment blanks were not practicable due to sampler type.

Data Group Numbers **(HCP PDS deployed April 7 – April 21, 2015, at Comal and San Marcos springs):**

Trip Blank 09 ***00759949***	HSM 470 ***00759948***

General Comments

Although some analytical issues are noted for the data group, unless otherwise noted in the detailed discussion, the data are considered valid for the purposes of the investigation. PDSs were deployed from June 1, 2015, through June 15, 2015.

Trip Blanks

There were no detections in the trip blank associated with these samples.

Equipment Blanks

Equipment blanks were not practicable due to sampler type.

Data Group Numbers **(HCP PDS deployed August 13 – August 27, 2015, at Comal and San Marcos springs):**

Trip Blank 10 ***00767214***	HSM 470 ***00767213***

General Comments

Although some analytical issues are noted for the data group, unless otherwise noted in the detailed discussion, the data are considered valid for the purposes of the investigation. PDSs were deployed from August 13, 2015, through August 27, 2015.

Samples were analyzed on two different instruments, one of which had an elevated TPH background. The TPH detections in samples HCS 440, FDHCS 440, HCS 460, and HSM 440 may be biased high. An unused sampler analyzed on this instrument was found to have 0.65 μg of TPH.

Trip Blanks

There were no detections in the trip blank associated with these samples.

Equipment Blanks

Equipment blanks were not practicable due to sampler type.

General Comments

Although some analytical issues are noted for the data group, unless otherwise noted in the detailed discussion, the data are considered valid for the purposes of the investigation. PDSs were deployed from December 1, 2015, through December 15, 2015. The PDS from HCS460 was not recovered.

Trip Blanks

There were no detections in the trip blank associated with these samples.

Equipment Blanks

Equipment blanks were not practicable due to sampler type.

Relative Percent Differences between Field Samples and their duplicates

Relative Percent Differences (RPD) values for parent samples and associated duplicate samples are provided in Table 2 below. In general, the RPD are less than 20% indicating parent and duplicate sample constituent concentrations are similar. Some differences observed in water samples may be the result of concentrations that vary naturally due to stream flow. Because the streams sampled are constantly flowing, constituent concentrations can change or fluctuate during the time period in which multiple sample bottles, which are all part of the same sample, are filled. Although sediment sample cores were collected in close proximity to one another, soil concentrations may vary spatially, which can cause differences between parent and duplicate sample constituent concentrations.

The differences observed do not show wide variations where a parent sample concentration exceeds a regulatory threshold or comparison value and a duplicate does not, or vice versa.

It should be noted that the RPDs between parent and duplicate field samples not only show differences between the parent and duplicate samples but also include differences inherent to laboratory procedures when the two separate samples are analyzed. Therefore, the laboratory RPDs contribute to the parent and field duplicate constituent concentration RPDs.

Table 2. Relative Percent Differences between Field Samples and their duplicates

B - Analyte detected in the laboratory method blank at the quantity listed

BV,BU - Sample exceeded hold time

H - Sample exceeded hold time

J - Result above the method detection limit but below the reporting limit

Method detection limits or reporting limits were used to calculate RPD for results not detected above these limits.
